VOLUME 36

JANUARY-DECEMBER, 1953

EDITORIAL AND BUSINESS OFFICES
2642 University Avenue - - - - - - - - - - - Saint Paul 14, Minn.

BUSINESS MANAGER
J. R. Bruce / R. R. Rosell

Copyrighted 1953, by the
MINNESOTA STATE MEDICAL ASSOCIATION

Index to Volume 36

A

Abdomen, A study of masses in the right lower quadrant of the, 481
Accidents—chief killer of children, 1141
Acidosis, ammonium chloride, Danger of, 133
Acute cervical tumor in a mentally deficient child, An, 1253
Aged, The responsibility of the practicing physician and health department in the care of the, 137
Alexander, H. A.: Injection therapy of varicose veins using sylnasol foam, 1249
Allen, William, Storey, Emerson W., and Rosenfield, A. B.: Accidents—chief killer of children, 1141.
Allergic reaction to para-aminosalicylic acid, 850
Allergy, Dermo-fungous, 602
Ammonium chloride acidosis, Danger of, 133
Analysis of tuberculosis case registers in Minnesota, 486
Anemia, Hemolytic, 128
Anemia, Treatment of, 40
Aneurysm of the aorta, Dissecting, with neurological complications (case report), 625
Ankle, Occult dislocation of the, 1135
Antibiotic therapy, Fatal enterotoxic reactions caused by, 63
Antibiotic therapy in bacterial endocarditis, 466
Aorta, Dissecting aneurysm of the, with neurological complications (case report), 625
Approach toward the ideal in parenteral nutrition, An, 221
Arterial embolism, peripheral, The diagnosis and management of, 230
Aspiration biopsy of bone marrow, 961
Atelectasis in the newborn, Surgical approach to, 172
Auricular arrhythmias, Quinidine intoxication occurring during therapy of, 1052

Cortone®

ACETATE

(CORTISONE ACETATE, MERCK)

The many indications for CORTONE *highlight its therapeutic importance in everyday practice*

Primary Site of Pathology and Indications

1. EYE—Inflammatory eye disease. **2. NOSE**—Intractable hay fever. **3. LARYNX**—Laryngeal edema (allergic). **4. BRONCHI**—Intractable bronchial asthma. **5. LUNG**—Sarcoidosis. **6. HEART**—Acute rheumatic fever with carditis. **7. BONES AND JOINTS**—Rheumatoid arthritis; Rheumatoid spondylitis; Acute gouty arthritis; Still's Disease; Psoriatic arthritis. **8. SKIN AND CONNECTIVE TISSUE**—Pemphigus; Exfoliative dermatitis; Atopic dermatitis; Disseminated lupus erythematosus; Scleroderma (early); Dermatomyositis; Poison Ivy. **9. ADRENAL GLAND**—Congenital adrenal hyperplasia; Addison's Disease; Adrenalectomy for hypertension, Cushing's Syndrome, and neoplastic diseases. **10. BLOOD, BONE MARROW, AND SPLEEN**—Allergic purpura; Acute leukemia† (lymphocytic or granulocytic); Chronic lymphatic leukemia.† **11. LYMPH NODES**—Lymphosarcoma†; Hodgkin's Disease†. **12. ARTERIES AND CONNECTIVE TISSUE**—Periarteritis nodosa (early). **13. KIDNEY**—Nephrotic Syndrome, without uremia (to induce withdrawal diuresis). **14. VARIOUS TISSUES**—Sarcoidosis; Angioneurotic edema; Drug sensitization; Serum sickness; Waterhouse-Friderichsen Syndrome.

†Transient beneficial effects.

CORTONE *is the registered trade-mark of Merck & Co., Inc. for its brand of cortisone.*

Apresoline T. M.

Hydrochloride
(brand of hydralazine hydrochloride)

for Control of Hypertension

FOR better individualization of dosage with Apresoline, a new, 10-mg. tablet has been added to the 25-mg. and 50-mg. potencies.

Apresoline is a relatively safe, *single* antihypertensive drug with minimal side effects, providing benefits in many cases—complete control in some. It is recommended that Apresoline be used in severe hypertension and in those mild hypertensive patients who have not been adequately controlled by conventional regimens (diet, mild sedation, rest, etc.). The following considerations are important:

Effective in essential hypertension with relatively fixed levels, early malignant hypertension, toxemias of pregnancy, and acute glomerulonephritis.

Induces gradual and sustained reduction of blood pressure with no dangerous, abrupt fall on oral administration.

Affords uniform rate of absorption and marked antihypertensive effectiveness.

Increases renal plasma flow in marked contrast to the decrease associated with certain other hypotensive drugs.

Produces significant relaxation of cerebral vascular tone without decrease in cerebral blood flow.

Side effects are minimal and often disappear as therapy is continued.

Complete information regarding manner of use and clinical application available on request.

LIES

PRINTER

JONES

If it's the printer's fault he ought to be shot.

But looking at it from another angle perhaps it points to a moral.

Maybe it is like a lot of businesses where all the stress is on selling . . . and the collection of accounts, so necessary for sound progress, takes a back seat.

Are your affairs run along these lines . . . with volume the goal and collections secondary? If it is then you need to change your policy.

TO CHANGE YOUR POLICY USE THE PROFESSIONAL CREDIT PROTECTIVE BUREAU

The Professional Credit Protective Bureau is collecting hundreds of past due accounts for dental and medical men.

The Professional Credit Protective Bureau is one collection organization that sees that the patient pays direct to the supplier of medical services. In other words you PAY THE COLLECTION ORGANIZATION AFTER YOUR PATIENT HAS PAID YOU and neither you nor the debtor is embarrassed.

More than 50 leading trade associations . . . including many medical and dental organizations . . . are using this service as part of their service to members.

It will pay you to investigate this tried and true system. Use the attached coupon.

Professional Credit Protective Bureau
724 Metropolitan Bldg., Dept. MM 1-53
Minneapolis 1, Minn.

Please send me full details on the operation of your collection service.

right through the menopause

on oral estrogen therapy that imparts no odor or after-odor, no taste or after-taste

YOUR prudent and assuring explanations will help—clearing away the jungle of her doubts and fears. Then SULESTREX will help—in controlling the physical symptoms of the climacteric.

Years of search have given you SULESTREX—an odorless, absolutely pure, crystalline estrogen, chemically standardized for unvarying hormonal activity. Unexcelled—therapeutically *and* esthetically—these tiny uncoated tablets will never insult the breath or perspiration, never annoy with "after-taste."

A new report by Reich and associates[1] confirms and extends his conclusions from his pilot study[2]...

"*Piperazine estrone sulfate* (SULESTREX) *is a clinically effective oral estrogenic substance, easy to administer and extremely well tolerated. Its action is accompanied with an amazingly low incidence of side reactions.*"

175 patients were included in this latest study, 50 of whom received therapy to relieve postpartum breast engorgement.

Make your own test—on your next menopausal patient. One trial will give impressive argument for this newest advance in oral estrogen therapy. SULESTREX is available in 0.75-, 1.5-, and 3-mg. grooved tablets.

WELCH ALLYN **ANOSCOPE**

Welch Allyn has taken the initiative in presenting to the medical profession a set of well-lighted anoscope specula as attachments to the standard battery handle. The tapered obturators and specula are so designed that they can be inserted without discomfort. The specula are all interchangeable on the same light carrier and can be readily detached for sterilization. The offset obturator handle ring facilitates insertion and allows the doctor to manipulate the anoscope with one hand, leaving the other free for treatment. Shadow-free and brilliant illumination is provided by the regular WACO No. 2 lamp. These specula are available in small, medium and large sizes with apertures of 14 mm., 19 mm, and 22 mm., respectively.

WELCH ALLYN
DIAGNOSTIC SET

Providing the general practitioner as well as the specialist with a set to completely cover diagnostic or operating procedure, this set contains the No. 110 ophthalmoscope, No. 216 operating otoscope, and a set of new Nylon specula.

Sets are provided with either the large, medium, or penlite-size handle.

The No. 110 Ophthalmoscope is a May type head constructed with a prefocused optical system which makes it unnecessary to adjust the instrument for clear focus. It is also provided with a patented rotatable unit containing standard, pin hole, and slit apertures, as well as "white line" grid and red free filter. The pin hole aperture provides a constricted spot of light permitting examination through small, undilated pupils. The slit aperture assists in estimating the level of various areas of the retina. The red free filter provides a contrast between the blood vessels and their background. The "white line" grid can be used to determine size and locate accurately certain lesions observed.

The No. 218 Otoscope has a patented rotatable speculum holder providing greater operating space. No set screw adjustments are necessary and prefocused Waco bright Light lamps provide abundant allumination at the distal end of the speculum. With direct illumination there is no light loss from prisms or projection lenses.

AYERST, McKENNA & HARRISON Limited · New York, N. Y. · Montreal, Canada

Salt is what makes things taste bad when it isn't in them.*

Most people find foods unappealing and insipid without salt. Therefore, when salt restriction is indicated, the patient must be impressed with the importance of a salt-free diet and must adhere faithfully to a rigid regimen. "With the development of such preparations as Neocurtasal . . . the problem of palatability and a salty taste has been fairly well solved . . ."[1]

Neocurtasal®

"... trustworthy nonsodium-containing salt substitute"[2]

—lends the desired salty flavor to foodstuffs, and can be used in all salt-free and low sodium diets.

CONSTITUENTS: Potassium chloride, ammonium chloride, potassium formate, calcium formate, magnesium citrate and starch.

Lilly

ILOTYCIN

(ERYTHROMYCIN, LILLY)

DOSAGE: Adults—Total daily doses of 400 to 2,000 mg. are recommended, depending on the type and severity of the infection. Lobar pneumonia, bronchopneumonia, and some of the milder types of respiratory infections caused by organisms susceptible to 'Ilotycin' have consistently responded to doses of 100 mg. every four to six hours. For other infections, larger doses of 300 to 500 mg. every six to eight hours should be employed.

Children—6 to 8 mg. per Kg. of body weight every six hours. Therapy should be continued for at least forty-eight hours after the temperature has returned to normal and acute symptoms have subsided.

Available in 100-mg. specially coated tablets in bottles of 36.

THE MEDICAL SCHOOL IN RELATION TO MEDICAL PRACTICE IN THE STATE

CHARLES G. SHEPPARD, M.D.
Hutchinson, Minnesota

THE invitation to speak to you on this occasion was most unexpected and deeply appreciated. It never occurred to me at any time since I left this medical school seventeen years ago that I should ever return to speak to any of you who were my own professors in medical education. I feel very humble because of it.

However, over the past several years, during which time it has been my privilege to serve as an officer of the Minnesota State Medical Association, I have been cognizant of the fact that there has been a certain schism between the practicing physician, be he a specialist or general practitioner, and the medical school staff and faculty. The impression has deepened that something must be done to close this breech, and it seems that this which I say today should be but the first of many similar efforts by others interested in the problems to accomplish that purpose. I believe that the differences of opinion exist because of a lack of complete understanding of mutual problems.

In beginning this discussion it might be well to review for you briefly the organized medical activities as they exist outside of the University Hospitals. Some of you know this already and others may not. There are 3,896 licensed physicians in Minnesota. An additional 2,000 are licensed in Minnesota, but do not live in the state. Of the physicians residing in Minnesota 3,713 are engaged in active practice and over 3,000 of these belong to organized medicine, that is, are members of their County Medical Society and hence the MSMA and AMA. The basic unit of the MSMA is the County Medical Society. There are thirty-two of these in Minnesota, ranging from small single county societies with membership of as few as seventeen to larger single county or multi-county societies, the largest of which is the Hennepin County society. Each medical society is autonomous, except that its efforts must be within the Code of Ethics of the MSMA and AMA and its Constitution and Bylaws must parallel those of the state and national organizations.

Activities on a statewide basis are conducted by representatives of each county society who are elected as delegates to the House of Delegates, one for each fifty or fewer members of each of the component societies. There are seventy-seven delegates and seventy-seven alternates elected to the House each year. The House of Delegates in turn elects its own officers who are the President of MSMA, First and Second Vice Presidents, Secretary, Treasurer, Speaker, and Vice Speaker. The House of Delegates meets annually or on special occasions, as required, to transact the business of the organization, accept or reject reports of the numerous committees and make whatever recommendations it wishes to be carried out.

Also there are nine councilor districts into which the state is divided, and each councilor district nominates its own councilor to the House of Delegates who then, when elected, serves as the Councilor of the MSMA to conduct the affairs of the association between sessions of the House. This council meets each quarter and sometimes oftener and considers any situations which arise on which it feels it can pass without consulting the House of Delegates. It is then, in effect, the interim governing body of the association, and has its own chairman, executive secretary and le-

---

Read at the Staff Meeting of the University of Minnesota Hospitals, October 31, 1951. The address appeared in *The Bulletin* of the University of Minnesota Hospitals and Minnesota Medical Foundation, 24:115 (Oct. 31) 1952.

gal counsel. There are committees of the Council itself as well as about fifty Committees for the Association as a whole, who deal with all phases of medical economics and practice. These committees report annually to this House of Delegates, or in the interim to the Council. The Council makes major decisions of policy, and also makes recommendations to the House of Delegates which may be accepted or rejected.

Now the attitude of the overwhelming majority of doctors in the practice of medicine in Minnesota is in favor of private enterprise, and this in turn is reflected in these decisions in the House of Delegates. To witness this let me call your attention to the recent request by the House of Delegates for an evaluation of your cancer detection center. It was felt that certain members of your group had been using this center to further their own private practices, and it was resented and questioned. I haven't seen the report from the committee that was appointed to evaluate the center, if there has been one written, but I have read Dr. Diehl's statement of policy which came out recently, which I favor highly, and if carried out by your people here should prevent any further such criticism along this line.

The majority of doctors in Minnesota are engaged in general practice. In 1943, for instance, there were 1,800 of them as compared to 958 specialists. There has been considerable criticism of the attitude of certain people on your staff and faculty by those engaged in general practice because of the belittling attitude some of them have taken toward those in general practice. I have been told by some of the students that there was much discouragement for them to enter into general practice with the advice that they had much better go into one of the specialties. This attitude I deplore, first because I am a general practitioner, and secondly, because I firmly believe that a well trained general practitioner is capable of caring for 80 to 85 per cent of all illnesses, but must have the specialist's help for the solution to the other 15 to 20 per cent of the problems which confront him.

Fortunately there has been somewhat of a change in attitude in more recent years, so that more of the graduates coming out today are willing to go into general practice than was true 5 to 8 years ago when about 85 per cent of them were going into specialties. I will grant that medicine is becoming more and more complex, and because of this more and more specialties are developing. There is still, however, the fundamental art of the practice of medicine which must not be lost in the maze of complicated laboratory procedures and which can be taught to any alert medical student. Perhaps this art of the practice of medicine is being neglected somewhat here in the medical school. I have sensed that at least some of the recent medical students felt that their own undergraduate training was being neglected here because of your extensive graduate training program, so I submit to you that your primary function should be always the instruction of the undergraduate with secondary emphasis on your graduate program. You should, in my humble opinion, gear yourselves to turn out more, not fewer, men who are properly prepared and conditioned to go into general practice, and encourage that idea with all the means at your disposal.

Teach your staff a little more of the ethics of medical practice, as they should carry it on when they are finished so that the role or opinion of the referring doctor is not belittled to the patient who comes back home at times feeling that he is being cared for by a dud or numbskull. These derogatory remarks about previous treatment accorded a patient sent to the University Hospitals have occurred too many times and should be discouraged. I realize that this same practice is followed by men in private practice as well, and I don't condone it there any more than here. But those of us who are in general practice like to feel that we are rendering a real service to our patients and not just acting as first-aid boys to the specialists, whether here or outside the University staff or faculty.

There are many specialists who are engaged in private practice outside of the regular staff and faculty of the University. I believe that some departments within the University Medical School are not making as much use of these men as they should. I believe that your visiting staff should be utilized to as great an extent as possible to give as wide a variety of views on any subject under discussion as possible. In medicine there are usually several ways of accomplishing good results in any given patient. It is these different approaches to the solution of any patient's problem which should be brought out, rather than the teaching of one view only, as might be the case if a visiting staff member's advice and consultation are not sought. There may even be times when the visiting staff opinion is superior to that of the men on the full time University staff.

Here at the University Hospitals, where you have every aid to diagnosis at hand, the temptation is to utilize all these aids as much as possible. I believe there is a tendency to forget that all these things are not going to be available at a moment's notice to the man going out to practice among the people of rural America. That is why I would have you teach him how he can best make some of the more common diagnoses with a minimum rather than a maximum of laboratory aids; how he can use his eyes, ears, head, and hands to the greatest advantage. In other words, I would have you emphasize more the art of practice, as I have said earlier. I do not mean by this statement to de-emphasize the role of the laboratory, because certainly we could not get along without it.

I believe, too, that it would be advisable for the heads of departments, as well as those on your faculty of lesser rank to attend these rural seminars as frequently as possible. By doing so they can see the existing facilities with which medicine is practiced outside of the medical school and can meet the practitioners of the state, talk with them, and understand their problems better. I think your understanding of our problems, and, in turn, our understanding of yours would be increased tremendously. We might even give you some ideas for research problems which would be more practically profitable than some of those now engaged in. At the same time we certainly don't want to discourage any real basic research.

All along the line in medical school education, both graduate and undergraduate, the role of the doctor in his community should be emphasized. Because the physician entering into private practice in a community is at least as well educated, if not better educated than most others in his community, it behooves him to be of as great service as possible, even beyond his contribution to his community's health. The old time doctor was placed on a pedestal by his community, and if he behaved himself, was kept there, aloof to public activities. That day has gone, and he must enter into general community life as much as his time will allow, and many times at some considerable personal sacrifice. He has an excellent opportunity to assist in the fight against "creeping socialism," and should so do.

From what I have seen and heard, there is too much advocacy of a socialized system from some elements within the faculty itself, and most of this stems from the fact that many who so believe have never been in private practice, or who have made failures of their efforts at it, and so turn to maligning it in favor of the completely salaried practice of medicine for all. I am convinced that the great majority of your staff and faculty believe in private enterprise, but even one or two in a group as large as yours, if they speak loudly enough, can leave the impression with those outside that the majority is favoring a socialized regime. At least the seed of doubt is planted, and this is not desirable. I believe that as new members are added to your faculty, you should take in those who have had a successful private practice or at least become thoroughly acquainted with their philosophy of practice and exempt those who favor the socialistic setup. More of the graduates come out now with the idea that socialization of medicine and eventually of all walks of life is inevitable. These words have been put in their mouths by the subtle attitude of the socializer, who is patient, bides his time, and advances his position little by little as is witnessed by the changes in our own life in the past twenty years. All of Norman Thomas' Socialist platform of 1936 is now public law, due in part to our acceptance of the slogan "It's inevitable, so why fight it?"

The fight against socialism should be the fiercest fight in the medical school, as we are the first, or among the first, that the government planners would bring to heel. There are many problems as far as medical care costs that have not been solved, but given time and applied energy to the problems, they are and will be solved without excessive government intervention.

Now to another phase of undergraduate training which I think has been neglected. I believe it would be possible, probably in the premedical school course somewhere, to require a short course in business, especially as it is related to medicine with emphasis on methods of bookkeeping, medical records, et cetera, as well as a short course in legal medicine. There is no time for these subjects in the medical school, although there may be some time available during the senior year for discussion on fees in general.

Another suggestion which would be of inestimable value to the applicant for our medical school would be to acknowledge the names of the candidates who are acceptable sometime between December and April preceding the fall of admission.

There has been considerable criticism of waiting until the last minute to announce the names of these men, at times severely handicapping that individual who may have his application in here and desires to go here above all other places, but who, to play it safe, has his application in at other medical schools in the country.

The subject of training of auxiliary medical personnel has been a sore point for many years in Minnesota. I refer in particular to the nurses training program, as laid down by the Nurses Training school and the American Nurses Association, in which people in our own state play important roles. I realize that this is a very tender subject, but that only increases its importance in solution. The nurse shortage has not been solved. I have had the privilege of sitting in on the discussion of the MSMA Committee on Nursing, but have not had the opportunity of hearing the other side of the picture. From what I can determine, this committee is completely frustrated in its efforts to establish nurses training centers in small hospitals throughout the state, and unfortunately I am not familiar enough with all of their proposals to discuss the entire program as intelligently as I should. I do know, however, that an apparent stalemate has been reached between the two groups.

As I understand the situation, the doctors in some of our small communities feel that they and their nursing staffs are quite capable of teaching a girl the fundamentals of bedside care of patients in homes or hospitals, while those in charge of setting up nurses training programs are keeping the standards of such instruction unnecessarily high, and are thus blocking the efforts of the doctors to train more badly needed nurses. Now there must be a solution to this problem. The doctors on the State Association committee have worked long and hard in an effort to solve these problems, but have arrived nowhere. When the subject is mentioned to them now, many of them become positively apoplectic during the ensuing discussion. With all due respect to them and their long hours and days of effort to solve this problem, it might be better if a new group would tackle the problem. Heretofore no one has had the courage to ask them to relinquish their committee appointment and let a new group be appointed in an effort to relieve the obstruction. I do not for one minute believe it is all the doctors' fault, however, and would suggest that perhaps it is time for the nurses to reassess their position with the object in view of doing the greatest good for the community, even at some sacrifice of position or standard.

Don't misunderstand me. I appreciate fully the hard battle which the nurse has made to attain her present position, but I don't like to see her become only a supervisor of others' duties when her primary function is patient care. It may well be that small hospitals are not staffed nor could afford to be staffed to produce R.N.'s, but more help for bedside care must be obtained in some way, and it is up to the nurses to lead the way, rather than to be obstructionistic in their attitude. I'm probably pulling my own house and the nurses home down on my head, but I am impelled to speak frankly on this subject. Perhaps the University Nursing School should concentrate on producing teachers of nurses who would in turn be qualified to go out and supervise nurses training schools throughout the state to try to meet the need. There are, I am sure, a great many facets of this problem which I have not even touched, but I believe a start should be made to rectify existing conditions.

The other medical auxiliary groups which are in short supply are laboratory and x-ray technicians. The teaching is such at most schools here in Minnesota that a girl gets either laboratory training or x-ray training, but not both. Most small hospitals or doctors' offices cannot afford to hire two girls, one to do nothing but laboratory work and the other to do nothing but x-ray work. The two must be combined, and if possible in a shorter course than is now available. To become a registered technician now requires four to five years, I believe, including two years of academic training, which could possibly be eliminated in order to save time and expense of training and thus increase the supply of available people.

Many small hospitals find it impossible to obtain registered technicians because of the great demand, and hence have to rely upon graduates of so-called commercial schools of medical technology, who are not really thoroughly trained in laboratory and x-ray procedures. If the girl is intelligent, she can complete her training under the physician's guidance to a certain degree, but this is not the best way by all means. Some way must be found to increase the supply of competent technicians, either by establishing another shorter course here at the University or its affiliated hospitals, such as Ancker, General, or Miller, or by working out some arrangement with these commercial schools, so that their girls receive more adequate training. You can't afford to be stuffy about them, and not recognize and offer to assist them, since we in rural areas have to accept them whether we like it or not. Actually we find most of them quite satisfactory for many procedures. By having more and better training schools, and encouraging these graduates to go into rural communities, the practice of medicine in rural Minnesota could be improved.

The same thing might be said of nurse anesthetists, although here, I realize, a more thorough fundamental training in some aspects of medicine is really necessary. We have a most conscientious nurse-anesthetist in our hospital and are able to do many more operative procedures at home than we could previously.

A source of great irritation to the practicing physician who refers patients to the University hospital for care has been the great delay in getting out reports to him about the patient who has been discharged. This has improved some in the past year but still needs to be worked on a great deal. Such prompt reporting of diagnosis, treatment advised, et cetera, is absolutely essential to the family physician who must carry on after such patient's discharge, and will improve the University staff relationship with private practitioners immensely, as well as the family doctor's and University staff relationship with the patient, and both are of equal importance.

In my opinion, and it is shared by many others I know, the doctors of Minnesota are negligent in their financial support of the medical school. There is at hand an ideal medium for such support, the Minnesota Medical Foundation, and I would encourage all Minnesota Physicians, whether graduates of Minnesota or not is immaterial, to join and support this organization.

More scholarships are needed, and the doctors, through their medical societies and as individuals could supply all that are needed if they would. If we don't do it, the government will step in and do it for us, and we'll have no say in the matter. Research grants should be made available through the estates of deceased physicians, wherever possible, to help carry on essential work.

Almost every county society in the state carries out immunization programs in the public and parochial schools, with small fees attached to encourage preventive medicine. We in McLeod County have pooled these immunization fees into the Society's treasury and have found this to provide almost all of the money we ever need. Others could do the same if they wished, and some of this money could be used for scholarship purposes, and would certainly be a most excellent public relations maneuver.

I'm sure Dean Diehl would be very much surprised and probably even a little disappointed, if I didn't mention a favorite subject, that of preceptorship for medical students. I became interested in this subject at the time when such a high percentage of the graduating classes were going into specialties, and realized that if this trend continued we would soon have a plethora of men in the specialties. Hence, over the past three or four years I have discussed this idea with many of my colleagues throughout the state with the result that several resolutions have been passed by the House of Delegates of the State Medical Association encouraging the idea and requesting the University to look into the matter and bring about its accomplishment. My feelings about preceptorships were further strengthened after I had the privilege of discussing medical organizations with the senior medical students last spring.

I requested one of last year's seniors to give me his own criticisms of the curriculum as he experienced it. I should like to quote a part of his letter for what it might be worth.

"All in all I think that we got a pretty good all round training especially so since I have been able to compare it with some of the other training evident on our internship. I do believe that most of us sincerely regretted that our university does not have a preceptorship included in the curriculum of its medical school. Again comparing notes with the boys from Wisconsin I feel that we missed a valuable form of training for general practice. I personally feel that general practice is the only form of medicine that holds any great deal of interest for me, but I would certainly have welcomed a chance to see it in action.

"Of course I felt that there was too much stress on the unusual of medicine and not enough on the everyday problems which I would assume that one meets in a general field. While training is confined to a university hospital I do not exactly see how this can be overcome. It is entirely possible, too, that I will be glad in a few years that I trained in an institution where the stress was so placed since the rest may come easier than I now anticipate.

"There was absolutely no training in the realm of starting and handling a business. We did have some courses which were almost entirely superfluous and could easily be forgotten. I am sure that personnel is available that could enlighten us in such matters. Were I to start a practice on my own I would have almost no idea as to what equipment would be essential, what my fees should be, and other problems the answers to which might not make me a better physician, but might have a bearing on how soon I get a crippling ulcer.

"I do not feel that the criticism that we are taught to be too dependent on laboratory procedures in making a diagnosis is a very valid criticism. Only by actually seeing what certain physical signs mean in blood, urine, and chemical changes will such signs be fixed in our memory.

"These are only criticisms of the university in relation to our training for general practice, which is what I understood you to want. There are of course certain individuals on the staff who have a tendency to thumb their nose at anyone in general practice but I believe that on the whole the staff was very good in praising the general practitioner and the results which they so frequently attained under adverse conditions."

It was very encouraging to me to learn first of all that so many of the group with whom I visited intended to go into general practice, and secondly that they felt they would have been very much interested in taking a preceptorship had the opportunity been presented to them.

At this same time I was rather disturbed because of the fact that there were so many of them who felt that they were willing to go into general practice but did not wish to get out of larger urban centers. They felt that by going to Podunk Center, perhaps without a hospital, or even with a small one available within a few miles, that they would be greatly impaired in their practices, put at such a disadvantage that they did not wish to try it.

I don't know what has happened to the pioneering spirit which prompted our forefathers to settle in rural areas, where they had nothing to work with but their senses and a few meager drugs, but something of this kind must again be regained by the young man coming out into the country today.

Preceptorship, in my humble opinion, would afford those in rural practices, or even in general urban practice, to further sell the idea to these young men, so that they could go into rural areas with a great deal more confidence and willingness, after having been exposed to the practice for a period of time. They would find that perhaps they could practice medicine without all the trimmings which are sometimes desirable, but not always necessary. They would find also that where conditions did not come up to the standards which they desired to practice under, they would have the pleasure and joy of bringing them up by their own efforts, with the help of their communities.

I believe that the patient coming to the University Hospital as a part pay or county patient should receive the same consideration as any patient in a private hospital. This should certainly include a great deal of care in the ordering of x-ray and other laboratory procedures, with the idea of trimming costs whenever possible. I am sure you will agree that some of these are expensive and perhaps not altogether necessary, even if interesting. Over the last few years we have found that the boards of county commissioners are more and more willing to have us keep our county patients in local hospitals, rather than send them here, because of the increasing costs. We can keep them in most rural hospitals for far less than it costs here, and the patients themselves would rather remain nearer home.

Could we be of help to you people by sending in certain types of cases for teaching purposes? Could you send out periodic bulletins to all the state physicians with requests for certain categories of cases you would like to have sent in? We don't have any idea what your problems are. We certainly should know them, in order to be of assistance to you.

We who are out in private practice realize that you people probably have gripes about us too, and we would encourage you to be equally frank. I am convinced that by having a committee appointed from the medical school faculty and University hospital staff and a similar group from the State Medical Association, these and other problems could be worked out to the best advantage of all. Perhaps several joint committees would be necessary, one to deal with legislative matters, one with doctor-nurse-lab technicians and other auxiliary aid problems, et cetera. But let us sit down and really try to solve these problems and quit sniping at each other from across the fence.

THE CHANGING TREATMENT OF PULMONARY TUBERCULOSIS

THOMAS J. KINSELLA, M.D.
Minneapolis, Minnesota

THE TREATMENT of pulmonary tuberculosis has, over the centuries, undergone many changes and additions with the changing times. The introduction of the sanatorium treatment with prolonged rest, hygienic care and graduated exercise was a distinct advance and restored many individuals to health, particularly those with less extensive disease and without serious complications, especially large cavities. Those individuals unfortunate enough to have more extensive disease or serious complications occasionally recovered completely, but more often improved considerably and then reached a plateau beyond which they could not go without additional help.

The addition of collapse therapy measures offered renewed hope to many of the above patients. Artificial pneumothorax by Forlanini in 1882, phrenic nerve surgery by Stuertz in 1911, thoracoplasty by deC'erenville in 1885, Brauer and Friedrich in 1907, and Sauerbruch in 1909, intrapleural pneumonolysis by Jacobaeus in 1913, and extrapleural pneumonolysis by Tuffier in 1910, each adding its bit to improve the over-all picture. Thousands of patients recovered and were rehabilitated by the use of these additional weapons.

There were, however, many gaps to be filled. Tuberculosis itself frequently did not respond sufficiently to render the patient suitable for any of the collapse therapy procedures. Then, too, there was the ever-present danger of a flare-up or spread of tuberculosis following any surgical procedure, even some of rather minor nature. Wound infections and poor healing with sinus or fistula formation were to be expected if infected areas were entered. There were, likewise, shortcomings and complications of the various types of collapse therapy which had to be considered and reckoned with in the over-all picture of treatment. The frequency of clear pleural effusions and a 10 per cent chance of tuberculous empyema were expected complications of artificial pneumothorax, while a bound down lung and impaired lung function were frequent sequelae to its use and detracted from its over-all value. The complications of infection, migration, extrusion and expectoration of the various filling materials used in extrapleural pneumonolysis greatly diminished the value of this procedure. The unnecessary or unavoidable removal or impairment of lung function by the apparently simple procedure of phrenic nerve interruption not infrequently proved more of a handicap than a blessing to the patient so treated.

The occurrence of inadequate collapse, unclosed or reopened cavity, angulation and obstruction of partially stenosed bronchi and the persistence of symptoms from bronchiectasis detracted seriously from the over-all good picture resulting from thoracoplasty treatment. The unavoidable necessity of sacrificing good lung tissue in order to control a cavity, likewise proved a handicap to the patient. The complications encountered and a vivid memory of past tragedies tempered the surgeon's desire to perform more heroic procedures. Other types of thoracic surgery were developing rapidly with improvement in technique, in anesthesia, in blood replacement and in chemotherapy, but the treatment of tuberculosis seemed to have reached a standstill.

Then came the era of chemotherapy, and after it, that of the antibiotics. First, the sulfa drugs and later penicillin and others to control secondary infection and reduce the complications attendant thereon. Following this, the sulfones appeared, promin, promizole and diazone, with mild anti-tuberculosis activity *in vitro* and in experimental animals to raise the hope of the tuberculous patient who has ever been ready to grasp at straws and to accept, without hesitation, any new drug which might offer any hope of cure of his disease. The hope was short-lived, however, for it was soon found that their toxic effects, particularly upon the blood, outweighed their real therapeutic effect. Then the antibiotic streptomycin appeared with its remarkable effects on mycobacterium tuberculosis in culture and in animal experiments. It was used intensively and in large doses with good effect until its toxic effects on the vestibular portion of the eighth nerve were recognized and the efficacy and reduced toxicity of smaller doses discovered. Then, dihydrostreptomycin appeared as an apparent im-

---

Presented before the Minnesota Academy of Medicine, May 14, 1952.

provement until its toxic effect on the auditory portion of the eighth nerve became evident. In spite of these complications, marked improvement followed its use, with almost miraculous results.

The periods of treatment had been short and intensive, but soon recurrences of trouble began to appear. It was soon discovered that the mycobacterium tuberculosis was developing resistance against streptomycin, so additional chemicals were tried. Tbione (TB I) was welcomed and then PAS (para-amino salicyclic acid). These compounds, especially the latter, were an aid in the control of tuberculosis. Though less spectacular than streptomycin, they were tolerated fairly well by the patient. They were, however, far from the final answer. Many organisms also became resistant to their action, and then it was discovered that two of the substances used together had a better effect than either one alone. What was more important was that when streptomycin and PAS were used together, they could be used in smaller dosage, could be continued over much longer periods of time, and that the emergence of resistant strains of bacteria was, likewise, greatly delayed. To add to the favorable picture, another simple compound, isonicotinic acid hydrazide (INH) appeared as a cheap and readily available material with strong antituberculous properties. It was not a cure in spite of all of its favorable publicity, but was another distinct help although the organisms soon developed resistance against it. Also, it was a distinct boon to those patients who already carried streptomycin resistant organisms. It soon became evident that it, too, must be used in combination with PAS or streptomycin, or both, if delay in emergence of resistance was to be effected. Under combined therapy, many patients with very extensive tuberculosis who otherwise would never have become suitable for any type of surgery can now be successfully treated, and many of the complications previously encountered and justly feared have now been reduced to the point where they may be accepted as calculated risks.

The present treatment of tuberculosis consists of a program of bed rest plus chemotherapy planned to extend over a period of months giving streptomycin, one gram every third day, and para-amino salicylic acid, 12 grams daily, supplemented with growing infrequency by pneumoperitoneum or temporary phrenic nerve interruption. This is continued until maximum improvement has been reached with clearing of most or all of the reversible components of the disease. Surgery to eliminate cavity, inspissated cavity, caseous residues or bronchiectatic areas is then added in the hope that the patient may be able to control the smaller residues left behind and still be protected against future recurrences which so commonly come from the larger residual lesions. With the surgery completed, the patient is again returned to the sanatorium regime for a period of prolonged chemotherapy, the length of this course to be determined by his individual resistance, the extent and type of any residual tuberculosis, and his further response to therapy, as well as to the results of bacteriological studies. It must be clearly understood that no surgical procedure can remove all tuberculosis from a patient's body. Unless the patient possesses or develops resistance against the organisms with or without the help of chemotherapy, he will never be free from the danger of further trouble. Chemotherapy, under this program, has opened wide the field for more extensive and yet more conservative surgical treatment of pulmonary tuberculosis and its complications.

The thought of removal of tuberculosis, or a tuberculous focus, is not a new one. The Shakespearean "Out damned spot" of Lady Macbeth spoken in another vein might well apply to this disease. Surgeons have been doing this at a price in other portions of the body for years; the tuberculous kidney, tuberculous epididymis, tuberculous appendix and Fallopian tube, were successfuly treated by surgical removal, but not always without complications. The idea of applying such procedures to the lung were anything but new. Theodore Tuffier, in 1891, successfully carried out a resection of a tuberculous nodule from the upper lobe. Just how the lesion was diagnosed still remains a mystery for Roentgen did not discover x-ray until 1895. Subsequent attempts were not so successful.

It is not surprising, with the increasing use of resectional therapy for other types of lung disease, that, occasionally, tuberculous lesions were inadvertently resected, at times successfully, but not infrequently with unwelcome complications or poor results as illustrated by the lantern slides of a pneumonectomy patient from 1937. Others later, some of them done intentionally for known tuberculosis disease, were more fortunate as illustrated by the slides of another patient operated upon in the fall of 1940, before the advent of any chemotherapy or antibiotics, who is now alive and well some twelve years following her total pneumonectomy for tuberculosis. Failures and complications, however, were sufficiently frequent to prevent anyone in good conscience from recommending such procedures except under quite unusual circumstances.

With the advent of antibiotics and chemotherapeutic measures, which hold tuberculosis under control for a time at least, this whole picture has changed. The doors have been opened wide and definitive treatment of localized tuberculous disease or its complications is a standard part of our modern treatment of tuberculous disease of the lung. The earlier attempts were directed, naturally, at removal of disease previously treated by pneumothorax or thoracoplasty, or both, without a complete result in a patient accustomed to collapse, usually with one good lung and in good general condition except for the handicapping residue of tuberculosis. When it became evident that such lesions could be successfully treated without a prohibitive mortality or morbidity, attention was naturally directed to less extensive disease involving one lobe and as experience increased and courage and confidence developed, to segments of one lobe, isolated cavities or their caseous residues and even to smaller nodular residues of disease or bronchiectatic areas resulting from it. These are now done even in patients who are negative repeatedly upon sputum or gastric cultures for acid fast bacilli because we well realize that such reports occur commonly in patients under intensive chemotherapy. A patient may then be treated by a pneumonectomy, lobectomy, segmental or multiple segmental resection or wedge excision of a localized area or cavity. Our object, as always, is to remove, if possible, the most significant disease or its residues conserving all normal lung, if possible, so as to handicap the individual to the least possible degree. The localized resections are far more desirable functionally than many of the former collapse therapy measures because they conserve normal breathing space to a greater degree.

One of the fundamentals in this treatment and one of the safety factors for all this work lies in prompt obliteration of the pleural space about the resected area which calls for continuous removal of fluid and exudate and immediate and continued expansion of adjacent lung tissue. If it becomes evident that there will be free space left, a tailoring thoracoplasty to bring about its obliteration must be done at once if the situation has not been anticipated previously, and thoracoplasty carried out before the resection is done. Complications such as bronchial leakage, bronchial fistula, localized empyema pockets, and infected wounds do occur but they are, fortunately, not frequent and a number of them may be successfully treated. The incidence of tuberculous complications is much higher in the patients whose organisms are already resistant to the drugs used. For these patients, the administration of a new drug to which the organisms are not resistant will obviate the complications. Preliminary drug treatment to submerge the activity of the tubercle bacilli and to bring about as much healing of bronchial or pulmonary disease as possible before undertaking surgery is probably a most important factor in the avoidance of complications. The continuation of treatment following surgery for a long period of time adds much to the patient's chances of remaining well.

Under this program, it is now possible to attack bilateral disease, removing a segment or a cavity from one side and, subsequently, a segment or a lobe, or even an entire lung from the opposite side, if the patient's vital capacity and lung function will permit. Diabetic patients are all too prone to develop tuberculous disease of an extensive and bizzare type but have responded well to the above program. Likewise, also, Indians, Mexicans, Negroes, and other groups so frequently seen with extensive cavitating tuberculosis have responded favorably to this program. Even children with progressive primary or secondary tuberculosis with extensive cavitation, previously difficult or impossible to treat satisfactorily, can now be successfully treated and given a favorable outlook by local or extensive resectional therapy. This is well illustrated by the slide of an eight-year-old Indian girl from whom a large caseous tuberculous abscess was removed, and a slide of a four-year-old Indian boy subjected to total left pneumonectomy for a caseous pneumonic tuberculosis involving the whole left lung with huge cavitation, who is now in good condition a year and half following the operation.

The complications of previous disease or its treatment can, likewise, be relieved or reversed by direct surgical attack giving back to the patient function of lung tissue previously lost. A relatively normal lung trapped by the fibrin and fibrous deposits on its visceral surface following a hydrothorax or a pneumothorax of long duration may, at times, be successfully returned to improved function but probably not to its original state by the operation of decortication, peeling away the thickened layers which trapped the lung, and permitting it to expand to the chest wall. Simultaneous removal of the parietal deposits must also be done. A lung trapped by a chronic pyopneumothorax or a lung previously badly diseased by tuberculosis is a different problem again for, although at times it may be decorticated and expanded to fill the pleural space, its function already damaged by loss of capillary bed or by interstitial fibrosis, does not improve to a corresponding degree and it becomes a space-filling rather than a breathing organ. The diaphragm, its function impaired by previous temporary interruption of the phrenic nerve, or stretching by extensive pneumoperitoneum, can never be returned to its original state. While it may move, it will probably never regain its former efficiency, therefore, words of caution must be exercised in the use of these apparently simple procedures.

A good knowledge of respiratory physiology and an estimation and evaluation of lung function become of increasing importance in this field. Clinical judgment and evaluation of all available information is necessary for proper appraisal in many of these patients before subjecting them to surgical procedures. It is well to remember that the complete picture is oftentimes not expressed by laboratory units alone. To carry out an extensive surgical procedure upon a patient, leaving him a respiratory cripple, is not conferring a favor upon him because he may be better off with his disease and able to breathe and carry on than without his disease and with no exercise capacity.

Definitive surgical procedures, particularly resections of one type or another, have almost totally replaced the use of the indirect surgical procedures in vogue only a few years ago. Is it proper that this should have occurred? Thousands of patients recovered under pneumothorax and thoracoplasty therapy. Can the present procedures do as well or better? Time only will tell. There is an old axiom in treating tuberculosis that we must not evaluate our results in short periods of time as such evaluations are likely to be erroneous. The period over which the more recent types of therapy have been used is yet short, under two to three years. One can only say that the procedures appear to be logical, definitive and designed to conserve good lung. They have been done with a legitimate and very low mortality. There has been no mortality and very little morbidity from local wedge resections except where undertaken under desperation circumstances (two patients following local wedge resection of a cavity from the good lung with no function in the opposite lung). Segmental excision, likewise, carries an extremely small risk, yet a higher incidence of air leakage, hemorrhage and infection. Lobectomy has been attended by 3.36 per cent mortality and pneumonectomy by 13.17 per cent mortality over a total series back through 1937 before chemotherapy was available. The follow-up period following resection has been too short to permit any final figures. My impression is that they are very good and that the procedures are eminently satisfactory. Time only will give the final answer.

We have already seen a few patients who have developed a recurrence of tuberculosis in the same or other lobes, a few who have never converted to negative cultures, and a few who have developed bronchial fistulae, empyema, et cetera, but these have been in the small minority only. Will the future return to us more of these patients with an exacerbation of tuberculosis? I fear that it may. The earlier preoperative and postoperative drug therapy was not ideal in light of our present knowledge. Resistant organisms may still survive to plague us and the patient in the future. Do these individuals, under drug therapy, develop their own powers of resistance to the same degree that they formerly did under the older program, or have they been carried on crutches with chemotherapy for a long period to collapse in time when this support has been withdrawn? Can new drugs be developed fast enough to control the organisms as they become resistant to our present weapons? Will some of our present patients with resistant organisms infect others with organisms resistant enough so that these new patients will not respond to our present drugs? Could not a combination of some of our old with the newer therapy be used to advantage, say intensive chemotherapy of a prolonged type combined with judiciously adminis-

(Continued on Page 39)

THE PRESENT STATUS OF TUBERCULOSIS IN MINNESOTA

Beginning of Tuberculosis Control

A Preliminary Report

FRANCIS F. CALLAHAN, M.D.
Saint Paul, Minnesota

ACTIVE measures for treatment and control of tuberculosis actually began in Minnesota in the first decade of this century. The Legislature of 1901 authorized the Governor to appoint a Commission of three physicians to investigate the advisability of establishing a State Sanatorium. The Commission was composed of Dr. H. Longstreet Taylor, Dr. James L. Camp, and Dr. G. S. Wattom. A report and recommendations were made to the Legislature of 1903, and that body enacted a law authorizing the appointment of an Advisory Commission to be composed of five physicians. The members of the original Advisory Commission were: Dr. H. Longstreet Taylor, Dr. James L. Camp, Dr. G. S. Wattom, Dr. A. P. Williamson, and Dr. George B. Weiser.

The 1903 Session of the State Legislature appropriated $25,000 for the purchase of land and the construction and equipping of buildings for a State Sanatorium near Walker, Minnesota. Full power to manage, control, and govern the institution was placed under the State Board of Control, which was at that time the central social welfare agency for the state. With the approval of the Advisory Commission, the Board of Control purchased 616 acres of land at a cost of $7,565.

The original building was completed and the institution was opened to receive patients in December, 1907. The purpose of the State Sanatorium was the treatment of patients with incipient pulmonary tuberculosis who had resided in the state for at least one year prior to admission. The charge for treatment was $1.40 per day, to be paid by the patient, his relatives, or the county of residence.

County Sanatoria Established

After the opening of the State Sanatorium for the care of persons with incipient tuberculosis, the Advisory Commission developed a plan for the establishment of county tuberculosis sanatoria to isolate and treat cases of advanced tuberculosis. The Commission recommended that the larger counties build their own sanatoria and the smaller counties form districts of two or more counties to construct and operate institutions for the care of their advanced cases of tuberculosis.

This recommendation was carried out only in part. Many counties refused to join a sanatorium district and insisted on sending all of their tuberculosis patients, whether incipient or advanced, to the State Sanatorium. This necessitated additional construction at the State Sanatorium to provide units for care of all stages of tuberculosis. The counties belonging to a sanatorium district were known as "organized counties" and those sending their patients to the State Sanatorium as "unorganized counties." Through the years, the staff of the State Sanatorium has never been able to conduct a case-finding program or direct sanatorium follow-up care of their discharged patients because of the distance of the unorganized counties from the institution.

Between the years of 1912 and 1918, 14 county sanatoria were constructed and put into operation, with the state contributing 50 per cent of the cost of construction and equipment up to $50,000. Additional costs of construction and equipment since the opening of these institutions have been paid by the counties.

Originally, the cost for care at the county sanatoria averaged about $10 per week per patient, with the state contributing $5 or about 50 per cent of cost, for each county-pay patient. Through the years, as improved methods of treatment were initiated and the cost of wages, food and maintenance increased, the counties assumed the additional expense. The 1949 session of the State Legislature increased the state's contribution for the care of county-maintained patients from $5 to $7.50 per week. It is hoped that in the future the state will increase its support of county patients and return at least close to 50 per cent support with which the county institutions started.

Francis F. Callahan, M.D., is medical services chief of the Minnesota Division of Social Welfare. This agency supervises the operation of the Minnesota State Sanatorium near Walker, and the twelve county sanatoria located throughout the state.

Read at the May meeting of the Minnesota Academy of Medicine, May 14, 1952.

In 1943, the charges for county-pay patients at the State Sanatorium were revised and state aid for them was placed on the same basis as for patients of counties belonging to sanatorium districts. Since that time, a per diem rate for the State Sanatorium has been established annually on the basis of operating costs. Counties are charged the per diem rate minus the state aid of $7.50 per week.

TABLE I.

Sanatorium	Opened	Original Cost	Capacity 12-31-51	Census 12-31-51	Vacancies
Buena Vista, Wabasha	1917	$ 62,000	38	27	11

*Figures do not include persons admitted to contagion ward of Ancker Hospital as suspects for whom diagnosis of tuberculosis has not been established.
**Figures on Ramsey County and Anoka State Hospital not available.

In addition to the public sanatoria, a few small private sanitoria operated in the state for a limited number of years. One 50-bed institution at Pokegama in Pine County was opened in 1905 and discontinued in 1943. At the present time, the only private facility of any importance for the care of tuberculosis cases is a unit at St. Mary's Hospital in Minneapolis designed for surgical and other special services for tuberculosis patients.

Other Installations

With the opening of the Veteran's Administration Hospital in Minneapolis in 1927, 200 beds were added to the total number of tuberculosis beds in Minnesota. Approximately 150 present tuberculosis patients at the Veteran's Administration Hospital are residents of Minnesota.

In 1943, a full-time tuberculosis control officer was appointed to make a survey of all of the patients in mental institutions. This survey was inaugurated because of the exceedingly high death rate from tuberculosis among the patients of Minnesota mental hospitals and the large number of cases of tuberculosis developing among employes of these hospitals. The study led to the construction in 1950 of a 252-bed modern tuberculosis unit at the Anoka State Hospital for the mentally ill. Tuberculosis patients from all mental institutions are now transferred to this unit for treatment. Two auxiliary units of approximately 75 beds each have been added to the tuberculosis unit at the Anoka State Hospital in order to accommodate all of the active and suspected cases found in the state mental institutions as a result of case-finding programs conducted in these hospitals.

The Minnesota State Department of Health has collaborated with the state and county institutions in case-finding, follow-up control on discharged patients, as well as providing necessary laboratory examinations for sanatoria with inadequate laboratory facilities. In December, 1906, a regulation of the State Board of Health requested practising physicians in the state to report all cases of active tuberculosis, but this did not become law until 1913. In 1911, the State Board of Health authorized their epidemiologists to make routine examinations of tuberculosis cases as they did for all other communicable diseases.

Control of Indian Tuberculosis

For many years, the State Board of Health has pointed out the extremely high rate of tuberculosis among Indians. Tuberculosis, at least for the past 100 years, has been the major health problem for Indians. The care of tuberculous Indians is the responsibility of the federal government.

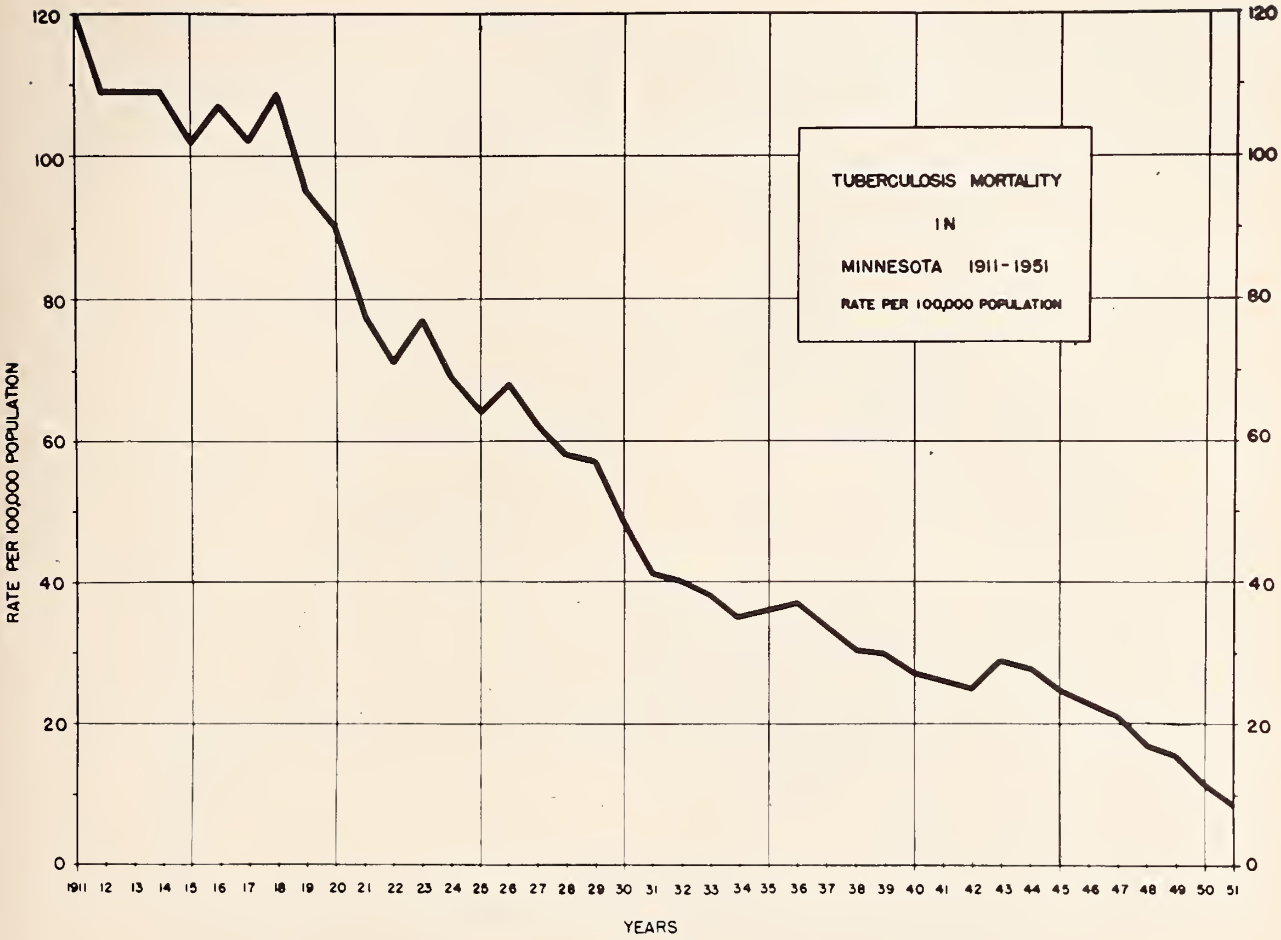

Fig. 1.

Largely through the efforts of Dr. A. J. Chesley, executive secretary of the Minnesota State Board of Health, and his co-workers, the federal government purchased land from the State Sanatorium and in 1934 constructed a 100-bed modern tuberculosis unit for the care of Indians at the State Sanatorium. This unit is operated by the Sanatorium staff and the actual cost of care given to the Indians in this institution is paid for by the federal government. The service is rendered on a contract basis, and the contract is readjusted and renewed from year to year. Since April, 1950, Out-Patient Clinics have been operated for case-finding and follow-up care of discharged sanatorium patients in the three Indian hospitals located at Cass Lake, Red Lake, and White Earth. These clinics were organized and are directed by Dr. E. A. Leggett of the State Sanatorium staff with the assistance of the medical and nursing services of the Minnesota State Department of Health and the federal Indian Medical Service.

Contributions to Case-Finding and Surgery

In reviewing the tuberculosis work since the Minnesota sanatorium plan has been in operation, it is timely to mention some of the contributions in case-finding that have come from within the state. In 1924, Dr. S. A. Slater[1] published a paper on the importance of tuberculin testing of school children in the Southwestern Minnesota Sanatorium District as a case-finding procedure. Briefly, his findings pointed to the fact that most positive reactors among school children acquired their infection either in the home or in school. This work of Dr. Slater's developed into the best case-finding program until the development of the mass x-ray screening. Even with the latter method, most tuberculosis workers feel that the tuberculin test should be used in conjunction with x-ray screening whenever possible.

In September, 1943, Dr. G. A. Hedberg and his co-workers[2] in St. Louis County started the first over-all x-ray screening program of normal citizens to be conducted in the state. The success of the St. Louis County program and that of screening programs at military induction centers led to the purchase of mobile x-ray units by the Minnesota State Department of Health. This was done with financial assistance from the U. S. Public Health Service. These units are operated throughout the state in all counties not having a mobile x-ray unit of their own. On occasion, State Board of Health and U. S. Public Health Service units have been used in counties having mobile x-ray units of their own in order to supplement county facilities in conducting massive tuberculosis surveys.

The Minnesota Public Health Association, now the Minnesota Tuberculosis and Health Association, organized in 1915, has been important in educating the public regarding tuberculosis. It has also conducted clinics in the unorganized counties in the state and has given assistance to the staffs of county sanatoria in their tuberculin testing and x-ray screening programs.

The Minnesota Trudeau Consultation Committee was organized in 1941 under the direction of Dr. A. J. Chesley. This committee visits sanatoria on invitation, offers consultative advice on the care and treatment of patients, and aids the sanatorium superintendents in procuring for their patients services that are not available in the patient's sanatorium of residence.

In order to make surgical care available to all patients in the state, a law was passed in 1941 which made it possible for a patient to be transferred to a sanatorium in the event he needed surgery which could not be performed in the sanatorium district of which he was a resident. The law provided that the cost of such surgical care would be divided equally between the state and the patient's county of residence. In 1945 the law was amended to include special diagnostic studies that were not available in the patient's home sanatorium. In January, 1951, the director of social welfare issued a regulation permitting the sanatoria providing such special services to make charges in addition to the non-resident per diem rate to cover complete surgical and special services.

Actually, the modern treatment of tuberculosis requires institutions specially equipped and staffed to care for pulmonary disease. The units of state government and medical groups especially interested in the control and treatment of tuberculosis are working together with the idea of bringing about the best over-all care of all tuberculous citizens of Minnesota as rapidly as possible.

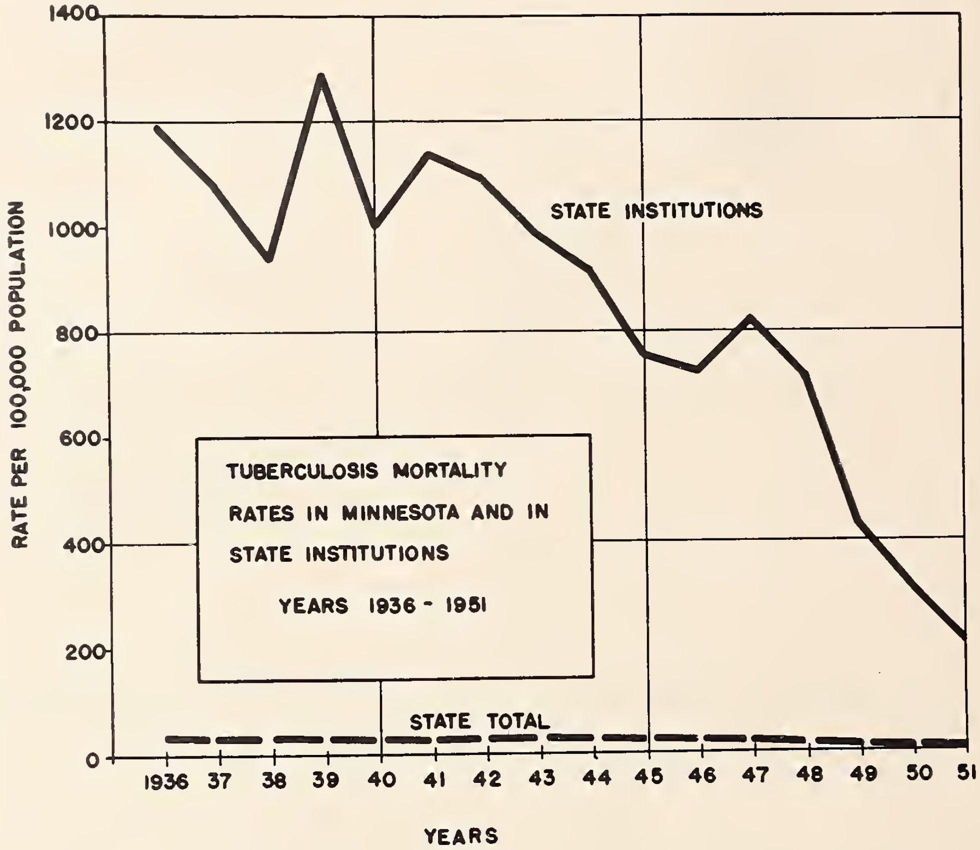

Fig. 2.

There has been a marked fall in the death rate from tuberculosis during the past five years. Undoubtedly, this has been slightly influenced by the change made in recording tuberculosis deaths by the Minnesota Department of Vital Statistics. However, along with the decrease in death rate, there has been a gradual decline in the number of patients receiving sanatorium treatment during this period.

By 1949, a large number of counties had been surveyed and it was felt that the time was right to introduce enabling legislation to discontinue or divert county sanatoria to other purposes. This enabling legislation was passed, and in 1951 Deerwood Sanatorium at Deerwood, Sand Beach Sanatorium at Lake Park, and Fair Oaks Lodge Sanatorium at Wadena were closed. At the present time, Sand Beach and Fair Oaks Lodge are operated as nursing homes for the aged and similar plans are in the making for Deerwood Sanatorium. Most of the tuberculosis patients in these institutions were transferred to the State Sanatorium and Nopeming Sanatorium, with a small number of Sand Beach patients going to Sunnyrest Sanatorium at Crookston. It is believed that it will be possible to close or divert more of the small county institutions in the near future.

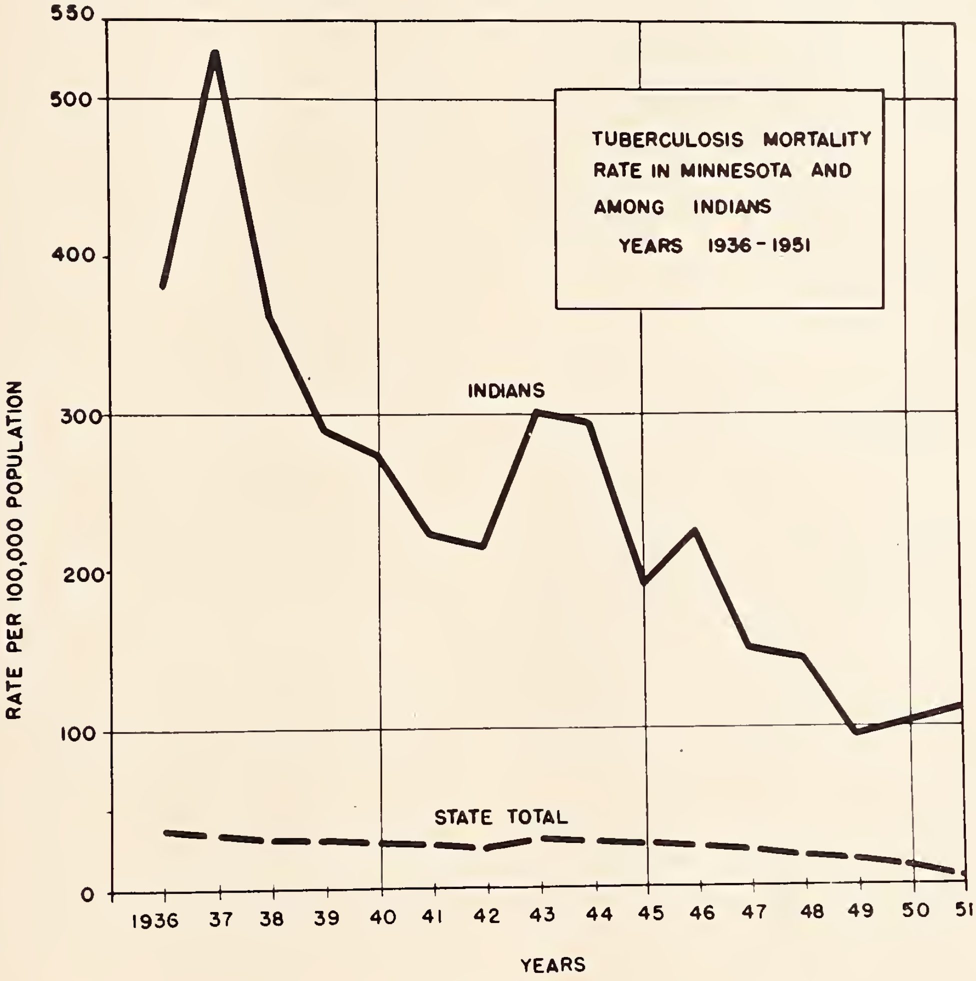

Fig. 3.

The case-finding and treatment program in St. Louis County has been so successful that it has created many vacancies at Nopeming Sanatorium. This has made it possible to send most of the active cases from several northeastern Minnesota counties to Nopeming for treatment, thereby creating vacancies at the State Sanatorium so that this institution should be able to receive the patients from other county sanatoria in northern Minnesota if and when they are ready to close.

Trends in Tuberculosis Control

The tuberculosis mortality rate in the state was over 100 per 100,000 population per year for the first decade of this century. It reached its highest point, 119.3, in 1911 and has declined steadily since, with the exception of two brief periods: the first during the influenza epidemic in 1918 and 1919; the second, during World War II between 1943 and 1945. The sharpest fall in the mortality rate during this century took place between 1947 and 1951, reaching its low point, 8.5 per 100,000 population, in 1951. Unfortunately, no accurate morbidity rates are available on a statewide basis at this time. If present trends continue, it would seem that adequate control, if not complete eradication, of tuberculosis should be achieved within a few years as far as the stable population of the state is concerned. However, there remains a hard core of tuberculosis types which will require special methods to control:

1. Recalcitrant positive sputum cases, who refuse to accept treatment over a sufficient period of time to arrest their disease. These cases constitute one of our greatest public health menaces as far as tuberculosis is concerned. They fall into four classes: psychopaths, alcoholics, criminals, and tramps. They are usually males and most frequently chronic alcoholics. While they are in the sanatorium, they are disciplinary problems and disturb the patients who are trying to get well. When they are out of the institution, they live in rooming houses, eat in restaurants, and patronize bars as long as their money holds out.

The problem of controlling and eradicating tuberculosis in this group of cases cannot be carried out on a voluntary basis. Separate quarters with proper restraints must be set up and maintained in one or more of the state institutions for the care of these people in order to protect the interest of the normal tuberculosis sanatorium patient and the health of the community at large. Attempting to treat patients from these groups in a standard tuberculosis sanatorium is simply a waste of the taxpayers' money unless these individuals know that they can be put in an institution from which they cannot escape if they do not conform to the usual sanatorium rules and regulations.

The state has adequate laws on the books to control these people but lacks proper facilities for their confinement. Dr. Albert Krieser, State Tuberculosis Control Officer for psychiatric and penal institutions, believes that a 50-bed addition to the Anoka Tuberculosis Unit, with private rooms that can be barred and locked, would provide satisfactory quarters for the treatment of all recalcitrant sanatorium patients, penal tuberculosis cases, and dangerously insane tuberculous patients.

2. It is felt by tuberculosis workers that displaced persons, most of whom come from countries in Europe heavily infected with tuberculosis, will have a much higher rate of breakdowns from tuberculosis than the normal population, even though they show no evidence of active disease when they are admitted to the United States. For this reason, it is believed that all displaced persons should be screened at least once a year for active tuberculosis over a period of five to ten years after their arrival from Europe.

3. The federal government provides for the care of persons who contract tuberculosis while serving in military units stationed in Minnesota. However, no provision is made for the care of their families. In order to protect its own citizens, provisions will have to be made in Minnesota for the immediate hospitalization of all service men's families who have positive sputums, where they will be isolated and under treatment while arrangements are being made for their transfer to their state of residence.

4. Migratory, agricultural, and industrial workers create another serious public health problem. When these persons contract tuberculosis, they are supposed to be returned for treatment to the states in which they have residence. Frequently, a great deal of time is lost in making arrangements for their return, and very often their home states either have no available tuberculosis beds or refuse to accept them for treatment. In the meantime, these persons live in boarding houses and hotels and create a serious public health menace.

The migratory chronic tuberculosis cases have been a public health problem in this country for years. Few of them have money and most of them believe that a change of climate would be the answer to their health problem. Most of these people have no technical or professional skills; and when they need money and food they almost invariably seek employment in restaurants because the work is light, they can keep warm and get enough to eat. It would therefore seem logical to set up some arrangement for yearly screening of restaurant workers and food handlers throughout the state. Without adequate control measures for the migratory and recalcitrant cases of tuberculosis, it is doubtful whether the incidence of this disease in Minnesota will fall very far below its present level.

Service-Connected Tuberculosis

A high percentage of Americans, particularly from this section of the country, have never had tuberculous infection before induction into military service. Thousands of these inductees serve in European and Asiatic countries where the incidence of tuberculosis is very high. Many of these men and women will have their first real exposure to tuberculosis in military service and a certain number of them are bound to develop active disease later on. In addition to x-ray examination of the chest, skin tuberculin testing on induction into, and separation from service should yield valuable information. When active disease develops in veterans who have been so tested it would give the best evidence of determining whether or not the individual's tuberculosis is service-connected.

General Comment and Summary

Great progress has been made in all phases of tuberculosis management during the past years. Many mistakes have been made, but on the whole the program has been good; and there has never been any relaxation of the effort of Minnesota tuberculosis workers to alleviate the lot of the tuberculous patient and to protect his family and neighbors. In the early days of the sanatorium program, the isolation of the positive sputum case was, in most instances, more important to the community than the actual treatment of the patient. Today, the tuberculous patients who can adjust themselves to a good sanatorium regime and complete the treatment prescribed for them are usually assured of a good clinical result.

The improvement in the treatment of tuberculosis has been brought about by several factors: (1) Better case-finding methods; (2) more adequate education of the public; (3) marked improvement in anesthesiology and surgical methods in the definitive treatment of pulmonary disease; (4) proper use of antibiotics, particularly streptomycin and other chemotherapeutic agents in both the medical and surgical treatment of tuberculosis; (5) rehabilitation started during and continued after sanatorium treatment.

While the results obtained in the treatment of tuberculosis during the past few years have been good, this is no time to adopt an attitude of complacency. Total war or other national catastrophe that would disrupt the present program of care and bring about serious physical hardships to large numbers of our citizens could bring about a serious increase in this disease.

Conclusions

Minnesota should:

1. Establish a tuberculosis unit where recalcitrant and other uncontrollable positive sputum cases of tuberculosis can be kept under restraint until they are no longer public health menaces.
2. Establish a routine procedure for the immediate isolation of positive sputum cases who are not eligible for county or state care.
3. Increase state aid for county-pay patients in all state and county sanatoria.
4. Continue x-ray screening of the entire normal population.

THE CHANGING TREATMENT OF TUBERCULOSIS

(Continued from Page 32)

tered artificial pneumothorax? Many of the complications of pneumothorax were related to its injudicious use. Is our present treatment the one which we will be using four or five years hence? I doubt it. The whole treatment of pulmonary tuberculosis at the present time is in such a state of flux that it is difficult to keep abreast of new developments. The broad outlook appears promising. We appear to be headed in the right direction, and we appear to be making ground, but we must keep ever alert for variations and improvements, and try to give our patients the best and most up-to-date treatment available in an ever changing field.

TREATMENT OF ANEMIA

FRANK J. HECK, M.D.

Rochester, Minnesota

KNOWLEDGE regarding the metabolism of iron has been accumulating for many decades and the past thirty years particularly have been fruitful in this regard. The experimental use of radioactive iron during the past ten years has allowed many studies that previously would have been impossible. All these studies are adding to general knowledge of the way in which iron is absorbed, utilized and excreted. The requirements of the body for iron can be divided into two main groups: (1) physiologic requirements for growth, for pregancy and lactation and for blood lost through menstruation; and (2) pathologic requirements when, as the result of loss of blood, increased amounts of iron are needed in order to maintain body metabolism, or when situations arise in which abnormal absorption or retention of iron may be present.

Until relatively recently, it was the normal view to consider that, after the period of growth had been attained in the male and after the climacteric in the female and in the absence of loss of blood, iron was held so tenaciously by the body that no further need existed for this element. Improvements in methods of research have pointed out that this viewpoint must be modified, since loss of iron occurs as the result of daily wear and tear by means of the loss of iron-containing cells throughout the body. This loss amounts to at least 1 mg. per day and it is quite possible that current investigations will lead to further revision in knowledge of the total normal loss of iron and will show that the amount of iron lost is considerably greater than was previously believed.

The average man who weighs 70 kg. has between 4.5 and 5 gm. of iron in his body. Of this amount, about 65 to 70 per cent is found in the hemoglobin of the blood and muscles, the latter constituting a relatively small amount. About 20 to 25 per cent of the total iron in the body is found in storage depots, such as the liver, spleen and kidney. The remainder is parenchymal, where it is not available for use as hemoglobin; in this form it is found in such material as cytochrome, catalase and peroxidase. The iron that is stored in such depots as the liver, spleen and kidney, is available for replacement of hemoglobin.

Normally, the average diet in the northern part of the United States contains 10 to 12 mg. of iron per day but of this amount, only about 10 per cent is absorbed. The iron is absorbed in the ferrous form by the mucosal cells of the gastrointestinal tract and is combined in the ferric form with apoferritin to produce ferritin. Definite limits are present as to the amount of ferritin that the cell can contain, so that these mucosal cells become physiologically saturated and no further iron is absorbed. When the amount of ferritin has decreased to the point at which the mucosal cells are no longer physiologically saturated with iron, then more can be absorbed from the intestine.

Iron is transported in the blood stream as serum or plasma iron. Under basal conditions, the amount of serum iron is relatively constant but a prompt rise is noted after oral administration of a single dose of iron, either in food or as a salt. Values for serum iron are decreased in states of iron deficiency and in patients who have anemia caused by infection, but are increased in patients who have pernicious anemia, hemolytic anemia, refractory anemia, hemochromatosis or hepatic disease. When the body needs iron, as in pregnancy and states of iron deficiency, the uptake of iron is increased to more than normal, whereas in diseases in which stores of iron are abundant, such as hemolytic anemia and pernicious anemia, little absorption takes place. After acute loss of blood, no sudden increase occurs in absorption of iron but apparently a lag is present because of the mucosal physiologic saturation that must be overcome before increased amounts of iron are absorbed.

As mentioned previously, a number of periods exist in which physiologic demands for iron are great. The greatest relative need for iron is in infancy when, because of relatively striking growth, the volume of blood is much increased and, therefore, the need for iron and hemoglobin

---

Read at the meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, May 27, 1952.

From the Division of Medicine, Mayo Clinic, Rochester, Minnesota.

is increased. After the first two years of life, the need for iron is fairly steady because then the rate of growth is slow and relatively uniform. Then at puberty, with accelerated growth, needs for iron are again increased in both the male and the female. The institution of menstruation introduces a second need for iron in the female. Furthermore, in the female an increased physiologic demand for iron is present during pregnancy and lactation. Thus, it is to be expected that hypochromic or iron-deficiency anemia would be seen more commonly at these periods, particularly if any abnormality of menstruation occurs or if an inadequate state of nutrition is present.

Hypochromic Anemia

The necessity and desirability of careful investigation of patients who have hypochromic anemia in order to determine the source of the anemia have been universally emphasized. This is particularly true for male patients but an adequate explanation for the anemia of female patients should be sought for just as diligently. It must be admitted that at times no satisfactory explanation for the anemia can be found, or the cause of the anemia becomes apparent only after several years of observation of the patient.

The critical hematologic values at which patients are considered to be anemic vary from institution to institution or hospital to hospital. It is my impression that many perfectly normal women are encountered whose erythrocytes number approximately 4,000,000 per cubic millimeter of blood and who have a value for hemoglobin form 11 to 11.5 gm. per 100 cc. Likewise, my colleagues and I prefer to consider the lower limits of normal values for hemoglobin in the male to be between 12.5 and 13 gm. and it is only when values are less than these levels that the problem of anemia is considered seriously. It is always difficult to estimate what relationship a slight decrease in hemoglobin might have to the patient's fatigue and weakness; my observations make me consider that a decrease of at least 2 to 3 gm. must be present before symptoms of this kind can be attributed to the anemia. Also, it has been observed many times that patients in whom anemia develops slowly can adjust themselves so well to decreased values for hemoglobin that they are not particularly aware of fatigue and weakness; it is only after their hemoglobin has been increased to normal that they realize that what they considered to be a normal situation was actually one of considerable fatigue.

No definite rules can be laid down for the examination and investigation of these patients. The history of long-standing anemia often almost automatically excludes the possibility of any serious disease. From a careful history and physical examination, together with good judgment, the examining physician can determine the extent of the investigation needed. Obviously, anemia appearing for the first time in older men or women should receive an extremely thorough investigation. The type of anemia and the hematologic picture that accompany loss of blood or lack of iron from a nutritional standpoint are those of hypochromia; microcytosis, normocytosis or occasionally macrocytosis may be noted. If definite bleeding is found and corrected, in most cases cure will result automatically if the patient is receiving an adequate diet.

This process can be speeded up by the oral administration of iron. It should be emphasized that the result of treatment of hypochromic anemia with iron salts is positive and that there should be definite and continued improvement until the hemoglobin returns to normal. Whether or not administration of iron will lead to a response can be determined in most cases from the response of the reticulated erythrocyte. Just as in the treatment of pernicious anemia, if treatment is effective and if the initial level of hemoglobin is low enough, there will be a response from the reticulated erythrocyte which will reach its peak between the eighth and fourteenth days of treatment. The height of this response is never very great but will often run between 4 and 6 per cent and occasionally as high as 10 to 12 per cent. There should then be a steady increase in the hemoglobin to a normal value. After the hemoglobin has returned to normal, a long period is required for the stores of iron to be returned to normal since in iron deficiency states the increased absorption of iron apparently stops as soon as the demands of the bone marrow for increased hematopoiesis have been met. It becomes obvious then that if the response to iron therapy is not prompt, either the loss of blood is greater than the hemoglobin formed or, as can be more commonly assumed, the diagnosis and treatment are incorrect and a new start must be made to determine what might be wrong.

In some instances hypochromic anemia is apparently the result of failure of the mucosal cells to absorb iron. Instances of this type of anemia are rare. More often inability to tolerate the preparation of iron leads to discontinuance of its use. Certain preparations cause intestinal irritation in a much higher percentage of cases than other preparations do. Both ferric citrate and ferric ammonium citrate have a relatively high percentage of gastrointestinal reactions. For this reason, for many years now ferrous carbonate, ferrous sulfate and other ferrous salts have been utilized in the treatment of hypochromic anemia. Very often giving the medication with the meal will enable the patient to tolerate it and, likewise, starting with a small dose and increasing it gradually to the maintenance dose will enable others to tolerate the medication. A total dosage of 15 to 20 grains (1 to 1.3 gm.) per day of ferrous salt is adequate. I know of no data to support the thesis that liver extract or liver preparations of any kind are of particular benefit in the treatment of this type of anemia except for that amount of regeneration of hemoglobin which one would expect from the iron content of the liver. What little benefit might accrue from the use of liver extracts which have been especially prepared for this type of anemia do not give the patient sufficient benefit to warrant their expense.

For many years iron preparations have been available for parenteral use, particularly in the form of iron cacodylate as well as other types of colloidal iron preparations. These could be given in only relatively small amounts and use of some of the colloidal iron preparations was attended by a high incidence of reaction in the form of chills, fever, nausea, vomiting and pain. Because of the severity of reactions, many observers felt that there was no specific indication for ever giving iron parenterally. With the introduction of saccharated iron oxide preparations, or the so-called high molecular iron, it is now possible to give relatively large quantities of iron parenterally in a single dose and with little chance of untoward reaction. A number of these preparations are on the market at present but the indications for their clinical use are and should continue to be strictly limited for the following types of patients. 1. A few patients are so intolerant of iron that it is impossible for them to take it orally in any of its usual forms. 2. There are apparently too some persons who, though able to tolerate iron that is orally administered, seem to have some interference in the absorption mechanism in the gastrointestinal tract and, therefore, are unable to make available to the body the iron which is taken into the gastrointestinal tract. 3. It is conceivable that in very rare instances the parenteral administration of iron might be desirable in an attempt to restore the hemoglobin rapidly after loss of blood rather than to give the patient transfusions.

The mode of administration of these saccharated iron oxide preparations is very simple. Although there are several methods for calculating the amount of iron required to restore the hemoglobin, the simplest method is to calculate a need of 25 mg. of metallic iron for each 1 per cent deficit in the hemoglobin. The first injections of iron should be small, only 25 to 50 mg. of metallic iron, in order to determine whether the patient has any reaction. If no reaction occurs, the dosage can be increased to 100 mg. of metallic iron per injection and injections may be given as often as twice a day. In this way, large quantities of metallic iron can be introduced into the body in a relatively short time. The reactions which may occur are those which have been previously mentioned. The response to parenterally injected iron is rapid and the peak response of the reticulated erythrocytes occurs somewhere between the fifth and the twelfth or fourteenth day. An amount of iron in excess of that calculated for restoration of hemoglobin to normal is desirable when this method is used in order to provide a reasonable amount of iron for storage. It should be emphasized that indications for the intravenous use of iron are few and that in almost all cases of hypochromic anemia oral administration of iron will be satisfactory.

Other Types of Anemia

A great many of the anemias seen in practice have no relationship to either loss of blood or to nutrition. In these instances, the stores of iron in the body are adequate and there is no need for giving additional iron or any benefit to be derived from it. In such diseases as pernicious anemia or any of the hemolytic anemias, there are large quantities of iron in the body, usually far more than the average normal, and these are available for conversion into hemoglobin. Likewise, a great many anemias are seen which are the accompaniment of some other primary disease, such as the anemia which so commonly accompanies rheumatoid arthritis or the anemias seen in association with infections, glomerulonephritis or the various types of malignant lesions in which there is no loss of blood. In this group also are anemias commonly associated with the blood dyscrasias such as those seen in the various groups of the lymphomas or of the leukemias. Here there is no deficit in iron content in the body and the administration of iron orally cannot be expected to result in any benefit to the patient.

Pernicious Anemia.—Over the years, a great deal has been written about the differential diagnosis of the macrocytic anemias. In this part of the country, pernicious anemia constitutes about 95 to 98 per cent of all of the macrocytic anemias seen in practice. Due attention should be paid particularly to the cardinal symptoms of this disease: (1), the glossitis, (2), the typical constant glove and stocking type of paresthesia which occurs in a high percentage of cases, and (3), the diarrhea which occurs in a relatively smaller proportion of the cases. In addition to studies of the blood and a suggestive history, it is important that the presence of achlorhydria be established, preferably after the injection of histamine before the diagnosis of pernicious anemia is made. Failure to ascertain whether free hydrocloric acid is present or absent can lead to considerable embarrassment, particularly if free hydrochloric acid is demonstrated after the patient has been treated for a long period for pernicious anemia and then, because adequate amounts of free hydrocloric acid can be demonstrated, the patient has to be told that he does not have pernicious anemia. This can result only in resentment toward the physician who has advised the use of the liver extract. Although examination of the bone marrow has certain advantages, it is not a necessary preliminary in the treatment of patients with pernicious anemia.

An adequate history, the demonstration of macrocytic anemia and of the absence of free hydrocloric acid are from a practical standpoint sufficient evidence for advising treatment with potent material in the form of either a good liver extract or of vitamin B_{12}. Because of the increased association of carcinoma of the stomach and pernicious anemia, it is always desirable to have a roentgenoscopic examination of the stomach before treatment is started as well as at yearly intervals thereafter. The result of treatment of pernicious anemia with any type of potent material is almost always very effective. If the initial level of erythrocytes is less than 3,000,000 cells per cubic millimeter of blood, it is possible to determine, within a week as a rule, by study of the reticulated erythrocytes, whether or not the response to treatment is adequate. The height of the reticulated erythrocytes at the peak of the response, that is, between the fifth and eighth days, will vary inversely with the level of the initial counts. With inadequate initial dosage, a suboptimal response will be obtained so that in these cases a secondary increase of reticulated erythrocytes may be experienced. However, if initial therapy has been adequate and if adequate treatment is continued, no further reticulated erythrocyte response will be seen.

Patients with pernicious anemia can be divided into two groups for treatment purposes, (1) those who have anemia alone without neurologic symptoms, and (2), those in whom neurologic manifestations play a large role or are the primary symptoms. For the first group, for many years I have used 15 units of a good potent preparation of liver extract and have given this amount initially on three successive days. Then 1 cc. of this 15 unit material is injected once a week until the concentration of hemogloblin and the erythrocyte count have returned to normal. After this, the interval between injections is gradually increased. By observing the levels of hemoglobin and erythrocytes in the blood and the appearance of the patient, I can then determine what the interval should be between injections. It is ordinarily not deemed advisable to give the material at intervals longer than three or possibly four weeks since there is no particular advantage in attempting to make the interval as long as possible. For the patient who has neurologic manifestations, the initial dose is the same, then 15 units of the material are given at intervals of five to seven days and the patient is observed for improvement. At the end of two months, if improvement is not occurring satisfactorily, the amount of potent material given at each injection should be increased or the interval between injections should be decreased. This increased dose should be employed until all neurologic manifestations have disappeared and only then can a longer interval between injections be used. At the Mayo Clinic we offer our patients the opportunity to learn to give their own injections but warn them of the desirability of regular checks on their hemoglobin and erythrocytes as well as informing them of the necessity of increased amounts of potent material in the event of any intercurrent illness, or if they should happen to have a recurrence of any of the cardinal symptoms of their disease.

There is no reason to believe that vitamin B_{12} will not do everything that a good potent liver extract will do and by substituting 15 micrograms of vitamin B_{12} for the 15 units of liver extract, basically the same result will be obtained. Although folic acid will bring about a response in the blood in cases of pernicious anemia, in view of the fact that it will not control and even will permit the development of gastrointestinal and neurologic manifestations, the use of this material is essentially contraindicated.

Other Types of Macrocytic Anemia.—Other members of the group of macrocytic anemias are seen very rarely in Minnesota and the surrounding territory. Occasionally cases of nontropical sprue, the so-called pernicious anemia of pregnancy, and macrocytic anemia of infancy may be encountered. There is still variable opinion as to any single method of treatment in these cases. However, folic acid given orally will bring about a response in some of these cases in which previous trial of vitamin B_{12} has failed. The dose of folic acid is 5 to 15 mg. daily.

Summary

Iron therapy is indicated whenever anemia is due to a loss of blood or an inadequate supply of iron on a nutritional basis. Except in rare instances, the treatment should be oral administration of one of the iron salts, such as ferrous carbonate, ferrous sulfate, ferrous gluconate or any other ferrous preparation. Under unusual circumstances and in the rare instance in which the patient is intolerant of iron to the point that he cannot take it orally, iron can be given by the intravenous route with only slight risk of reaction. Iron is not of benefit in the treatment of the anemias of infection, malignant disease, rheumatoid arthritis, and so forth, unless loss of blood or iron deficiency on a nutritional basis is associated.

The treatment of pernicious anemias consists of giving potent liver extract or adequate concentrations of vitamin B_{12}. The amounts given depend on the type of involvement since patients with neurologic manifestations require much greater quantities of potent material in order to obtain benefit. The other rare macrocytic anemias, must be treated essentially on a trial basis to determine whether folic acid or vitamin B_{12} will bring about a response. In all cases, regardless of type, the importance of an adequate diet cannot be overemphasized.

CONFINEMENT OF TUBERCULOSIS PATIENTS

Even in a community with plenty of tuberculosis beds, it can hardly be expected that every patient with chronic tuberculosis and positive sputum be hospitalized indefinitely. For example, the intelligent and relatively asymptomatic elderly patient, unsuitable for additional therapy other than rest, retired on a pension and living in a home without children, can remain at home without excessive danger to himself or to others. The irresponsible bar fly, who finally persuades the tavern owner to let him wait on table or work in the kitchen to help pay for his drinks, clearly needs continued institutionalization of some type. Even where tuberculosis beds are limited, and when there is little to offer therapeutically, it is justifiable to use every reasonable means to confine such a patient to a sanatorium or hospital indefinitely.—Committee on Therapy, American Trudeau Society, *The American Review of Tuberculosis,* May, 1952.

COMMON OCULAR MANIFESTATIONS OF DIABETES MELLITUS

JOHN H. PETERSON, M.D.
Duluth, Minnesota

DIABETES may be accompanied by changes in nearly all the structures of the eye. The more serious changes are those which occur in the retina. Those changes in the retina which can be said to be due to diabetes alone are probably second in frequency to those occurring in the lens.[17] However, because of the common association of arteriosclerosis and hypertension with diabetes, the number of cases with retinal lesions is much greater than those showing other pathology.

Among the changes noted but of lesser importance are subconjunctival hemorrhages seen under the bulbar conjunctiva. These usually clear up spontaneously in a few days.

Changes in refraction are quite common in diabetes, especially among those in the older age groups. This may be evidenced by sudden decrease in visual acuity which had previously been normal or it may manifest itself by frequent small changes in visual acuity over short periods of time and result in the patient asking for refractions frequently. Needless to say, one should be careful about changing lenses for diabetics until their diabetic condition is stabilized. The cause of such refractive changes in the diabetic is not definitely known. One writer ~~Duke-Elder~~ feels that it is due to a change in the lens. He states that as the blood sugar rises, provided available water reserve is maintained, the osmotic pressure of the aqueous tends to decrease, largely due to the elimination of osmotically active substances from the blood in the increased flow of concentrated urine. The lens is a comparatively stable system, not readily participating in the fluctuations common to all body fluids, and, therefore, will tend to maintain its original molecular concentration. Therefore, in order to maintain osmotic equilibrium, fluid will tend to flow into the lens from the chambers of the eye. The lens will then swell, causing an increase in its curvatures with a resulting myopic change. With a fall in blood sugar, a reverse in osmotic flow occurs and a hyperopic change occurs. One should always suspect diabetes when unexplained sudden refractive changes occur, especially in the adult.[4]

The ability to do sustained close work may be impaired in the diabetic because of a weakened ability of the eye to accommodate. In some, attempts to do close work are followed by headache, blurred vision and vertigo. The condition may improve on treatment of the general condition but often these people may have to use a stronger lens than usual for close work.[18]

Occasional cases of paralysis of an extraocular muscle are noted in this disease. They are thought to be due to a neuritis affecting the nerve supply of the muscle or to a thrombotic lesion involving the ocular nuclei. The sixth nerve is most frequently involved with a resulting paralysis of the lateral rectus muscle. One eye only is usually involved. The resulting diplopia is usually exaggerated on turning the eyes to the affected side. The condition may last a long time but usually returns in two or three months to a normal state. The oculomotor and trochlear nerves may also be involved with paralysis of the muscles they innervate and supranuclear involvement may also develop with paralysis of upward and downward movements and convergence.[5]

In the iris the most frequent diabetic changes occur in the pigment epithelium and are characterized by edema, swelling and degeneration of the epithelium, with liberation of free pigment. The stroma is not ordinarily affected but in some instances may also be edematous and atrophic. Evidence of degeneration may also be found in the sphincter, dilator and ciliary muscles in this condition.

In rare cases of diabetes the condition Rubeosis Iridis is found. This is characterized by a proliferation of new vessels on the surface of the iris in the form of a ring around the pupillary border. Gonioscopic examination will often show large vessels running peripherally into the angle where they break up again into many branches connecting with Schlemm's canal and forming anterior synechia. A recurrent hyphema and glaucoma are commonly associated with this condition. The glaucoma responds very poorly to the usual

Read at the Annual Meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, May 27, 1952.

procedures used for reduction of the tension. Histological examination of these cases has shown that the new vessels were not associated with inflammation or new tissue but lie in and upon the iris itself. The choroidal vessels are often dilated and in either region there may be extravasations of blood.[6]

A diabetic iritis is mentioned in the older literature but of late years most authorities feel iritis in diabetics is due to some intercurrent infection. We have had several cases of iritis recently which responded very poorly to the usual treatment. On further examination of these cases mild diabetes was found. As soon as the diabetes was treated also, the condition cleared readily. Some cases of serous iritis in diabetics seem prone to develop hyphema. One should always suspect hyperglycemia when hemorrhage is seen in iritis.

The occurrence of cataract among patients suffering from diabetes is quite common. The reason for this is not definitely known. Many of these people are in the age group when ordinary senile cataract may be found. O'Brien found that the normal blood sugar level was disturbed in about 50 per cent of 238 cases of senile cataract. He felt that the higher than normal concentration of sugar in the fluids surrounding the lens over a period of years may lead to the development of cataract.[14]

The typical diabetic cataract is the opacity occurring in younger diabetics. They are of ~~two~~ 2 5 general types. They are usually present in both eyes but more advanced in one. In one type there are numerous fine punctuate snowflakelike opacities in the anterior and posterior cortex close to but not immediately beneath the capsule. Sometimes iridescent granules are associated with the opacities. The other type is a posterior saucer shaped subcapsular opacity composed of confluent granules. However, the two types may be present in the same lens. These cataracts often develop over a period of months but in some young diabetics they may develop in a period of weeks or less where the diabetic control is poor and by institution of vigorous treatment of the diabetes they can often be greatly reduced or eliminated completely.[12]

O'Brien and Allen in a series of 260 young diabetics under twenty-one years of age, found 13 per cent had cataracts. In each instance the diabetes was poorly controlled for months or years before the cataract developed. They reported arrested development after satisfactory control. Waite and Bethume, in a series of 2,870 diabetics under twenty-one years of age, found opacities in 4 per cent. These were all severe diabetics. Fifty per cent of those with cataracts were out of control when first seen. The remainder of the cataracts developed in spite of good treatment.[15]

Priscilla White found cataract in 1.4 per cent of 2,191 diabetics and feels that they are due to poor control.[19]

Mars reported a series of sixty-one cases of juvenile diabetics of ten to twenty years' duration. There were no cataracts in his series. They were a group of diabetics well controlled from the beginning of the disease. He feels that there is no definite evidence of increase of cataract with increase in the age of a patient or duration of the disease, and that with good control there is definitely a decrease in the percentage of opacities. The treatment of cataract once developed in the diabetic is similar to that in any other individual. The diabetes should be well controlled before operation as the incidence of hemorrhage postoperatively is higher in diabetics than in the normal.[12]

Lipemia retinalis is certainly not a common finding in diabetes but perhaps should be mentioned here. Lipemia, a condition where the blood is altered in its appearance by the presence of fat in an emulsified state, is found in diabetes, alcoholism, starvation, phosphorus poisoning and xanthomatosis. However, it is only in diabetes that the changes can be seen in the retinal vessels. Eighty per cent of the cases have been reported in the female and the average age is twenty-five years. Most of the patients have severe acidosis at the time. Clinically the condition is first observed in the periphery of the fundus where the vessels become milky and hazy in appearance and gradually this spreads towards the disc. The arteries and veins gradually become flat and ribbon-like in appearance. In some cases the vessels near the disc are salmon-colored at this stage. In some cases there is a more yellow color to the vessels and often there is seen yellow-white stripes accompanying the arteries and veins as if the perivascularis were infiltrated with fat. In all cases the light reflex from the vessels becomes diffused or lost. The disc and remainder of the fundus are usually normal. In the worst cases the vessels become dull ivory in color and the fundus tends to become lighter in color due to similar changes in the choroidal vessels. When the condition clears up the periphery is the last to become normal in appearance.[7]

The most common and serious eye complications of diabetes are those occurring in the retina.

It is often difficult to determine whether or not the changes found in the retina of diabetics are entirely due to diabetes or whether they have been modified by some intercurrent disease such as sepsis, hypertension or nephritis.

The earliest and most characteristic early diabetic changes in the retina are the small round red spots found in the posterior pole of the eye, usually near the macula. They were formerly thought to be small hemorrhages but have been proved by Ballantyne[3] to be microaneurysms. This work has been confirmed by Friedenwald[8] and Ashton.[2] These spots will at times show a central light reflex on ophthalmoscopy, and are usually found in the inner nuclear layer. They vary from thirty to ninety microns in diameter. At this stage one may see small and larger round hemorrhages which are due to rupture of the aneurysmal walls and some which are deeper and confined to the outer molecular and outer nuclear layers. These appear to be from the plexus of capillaries at the outer boundary of the outer nuclear layer. Some of these microaneurysms undergo a process of thrombosis and cicatrization with formation of a small white spot seen ophthalmoscopically. Exudates are seldom seen clinically in the early changes previously mentioned but Ballantyne has seen clumps of albuminous material histologically in the middle and deeper layers in the earliest stage.

It is not uncommon to find the microaneurysms alone near the macula clinically. At a little later stage small hemorrhages and white dots may appear. The latter are never found without the aneurysms. The nature of the discrete white dots is not entirely known. Some are thought to be due to hyalin and fatty changes in the thrombosed microaneurysms and others to be homogeneous masses of hyalin and albuminous material surrounded by fat in the internuclear layers. Some of the latter tend to increase in numbers and coalesce and probably form the larger waxy patches seen at later stages of the retinopathy. In the condition up to this point it is rare to find ophthalmoscopically visible signs in the retinal vessels, but they are often a feature of the histology of the capillaries. Here Ballantyne found minute fat granules in the endothelium of the capillaries and this was occasionally associated with swelling of the endothelial cells. In some cases the capillary walls appear thickened and of a hyalin nature. There has been much speculation as to the significance of the findings.

Occasionally, at this stage, in addition to the above findings ophthalmoscopically, one may see soft cotton wool like patches. These patches when seen without evidence of arterial disease probably represent a toxemia from some intercurrent infection. After removal of the toxic process they tend to disappear.[20]

In an occasional diabetic with hypertension the fundus will show only signs of vascular hypertension and will be of no aid whatever as far as diagnosis of diabetes is concerned.[10]

Further changes in the retina in this condition are evidenced by changes in the veins, new formed vessels, periphlebitis, phlebosclerosis, increasing hemorrhage in the retina and vitreous, massive exudates, retinitis proliferans and retinal detachment. Ballantyne found the above changes in sixteen of 178 cases in his series of diabetic retinopathy. The above changes do not necessarily follow in sequence in diabetic retinopathy but they are always at least preceded by the formation of microaneurysms.[3]

The venous changes not associated with new vessel formation are characterized by, first, intermittent enlargement of the veins fairly close to the disc and usually in the principal veins. This has been described as beading or lateral knobs or buds from the veins. Also one may see overfilling and increased tortuosity of the veins which is not uniform in distribution and is limited to individual branches or segments of the veins. Yellow-white exudate may occur along the wall of some of these veins giving a sheathed appearance while others appear to be completely obliterated and the vein appears white and uniform in contour, peripheral to the thrombus. Hemorrhages may be associated with these sclerotic changes. These changes have been called phlebosclerosis because they resemble the changes in the arterioles in arteriosclerosis.[9] Three main types of retinal phlebosclerosis have been described: (1) the intimal type with venous thrombosis and fibrosis; (2) the medial type in the wall of the vein giving dilatation and constriction of venous segments resulting in a beaded appearance as a result of hyalin changes in the media; and (3) the adventitial type where changes occur secondary to changes outside the vein. Here a connective tissue sheathing occurs after subsidence of inflammation or edema. Ballantyne believes that the pale sheathed appearance of some of these veins is due to a fatty accumulation about the vein walls. Wagner stated that the yellow-white sheathing of some sections of veins in this condition is not explainable but believes it probably due to coagulated exudate in the perivenous spaces.

At some places in the retina where the altered dilated veins approach the surface the internal limiting membrane disappears and at these points one can see the origin of preretinal and vitreous vascular tufts.[3] The new vessels have a matrix of gelatinous appearing material with them on the surface of the retina and in the retina. This process is not typical of the usual retinitis proliferans which follow hemorrhage.[11] It is primarily a vascular growth and the supporting matrix is a primitive tissue which may arise as a metaplasia of the tissue of the vein wall. This preretinal vascular membrane can finally become organized and contract causing deformity of the retina and retinal detachment. Hemorrhage from these new vessels is rather common in the later stages of this condition. Still later in this disease one may find cystic degeneration of the retina, secondary glaucoma, secondary cataract, cholesterol crystals in the vitreous and subretinal fluid and further increases in the scleratic and fatty changes in the vessels.

Ballantyne found that thirty-eight of 176 diabetics with retinopathy had the so-called mixed type of retinopathy, that is, they had typical diabetic features plus changes of vascular hypertension including cotton wool patches, striate or flame shaped hemorrhages, and arterial changes. This type of retinopathy was usually seen in patients over thirty years of age who had had the disease for fifteen years or more.

There seems to be a great difference of opinion in the literature as to the value of good diabetic control in the incidence of diabetic retinopathy. Ballantyne and O'Brien felt that the one most important factor in its development was the duration of the diabetes. It was most often found in their series after ten to fifteen years of the disease, and was more often found among older patients who had had the disease this length of time. They cited examples of cases where the control had been poor and the retinopathy minimal or absent and cases where the control had been good and the retinopathy severe and concluded that poor control was not necessarily a factor in its development. During the past two years, however, Post and Strickle[16] and Anderson[1] and Maumenee[13] have shown that the incidence of retinopathy can be reduced and postponed by strict diabetic management. Anderson states, however, that in advanced diabetic retinopathy in the elderly patient the diabetic treatment should not be too vigorous and he should have a diet relatively high in protein to aid in repair of damaged ocular tissue.

URGENT SURGICAL CONDITIONS IN THE NEWBORN

ALVIN B. HAYLES, M.D.
Rochester, Minnesota

IN RECENT years great progress has been made in surgical care of newborn infants. This progress has resulted from improved surgical techniques augmented by better understanding of nutrition, fluid balance and metabolism of electrolytes. The pediatric surgeon, the pediatric nurse and the pediatrician working together as a team have been able to accomplish much for babies who, not many years ago, were considered to have hopeless conditions. Prompt and accurate diagnosis is of utmost importance in infants since many of the conditions to be discussed must have immediate surgical treatment if the baby is to survive.

It is the purpose of this presentation to review the cardinal diagnostic points in a group of diseases that are now amenable to surgical correction. No effort will be made to discuss all the conditions that may at one time or another require surgical intervention nor will surgical techniques be described. No attempt has been made to include fractures and injuries to the peripheral nerves that may occur in the newborn. For convenience and simplicity the conditions will be discussed by systems.

Central Nervous System

Subdural hematoma in early life is being recognized with increasing frequency.[9,20] It may or may not be associated with evidence of fracture of the skull or injury to the scalp. It is recognized much more frequently in the late part of infancy or the early part of childhood than in the neonatal period. However, physicians should be constantly aware of the fact that subdural hematoma may be encountered in the newborn child and that adequate treatment may prevent severe crippling deformities in later life. The frequency with which subdural hematoma is diagnosed is in direct relation to the index of suspicion on the part of the physician. In a typical case, respirations are difficult to establish soon after birth and cyanosis is prominent. Feedings are taken poorly and vomiting, although not always present, is usually a severe problem. The vomiting usually is not projectile as contrasted with that of intestinal obstruction. Lethargy is marked and varying degrees of shock may be observed. Convulsions or twitchings may be present. Physical examination discloses a bulging or tense fontanel and perhaps irregularity of the pupils or retinal hemorrhages. The normal neurologic responses of the newborn infant are depressed or absent.

Examination of cerebrospinal fluid may be carried out but frequently it is not of great help. The presence of gross blood in the cerebrospinal fluid does not necessarily indicate subdural hematoma nor does xanthochromic fluid indicate that the hemorrhage is confined to the subdural space. Some physicians consider that lumbar puncture benefits the baby and aids in the exclusion of the possibility of hemorrhage into the nervous system. A diagnosis of subdural hematoma is established by discovery of a blood-containing cyst by means of the introduction of needles into the subdural space through the lateral margins of the anterior fontanel. This procedure is not difficult but it is best carried out by a qualified neurosurgeon. When the diagnosis of subdural hematoma has been established, frequent taps of the hematoma become necessary until fluid fails to accumulate. The great majority of subdural hematomas in the newborn infant are bilateral so that the finding of a subdural hematoma on one side indicates search for a similar lesion on the opposite side. If subdural hematomas can be evacuated completely by a series of subdural taps, improvement will be striking and prompt. Unfortunately, removal of the fluid by this relatively simple technique does not mean cure of the condition; in some cases it may be necessary for the neurosurgeon to do a more extensive procedure in which the residual sac is freed from the brain in the hope that this procedure will prevent contracture, scarring and symptoms in later life.

Hydrocephalus in the newborn baby may be so severe as to prevent delivery of a living child.

From the Section of Pediatrics, Mayo Clinic, Rochester, Minnesota.

Read at the Annual Meeting of the Southern Minnesota Medical Association, Austin, Minnesota, September 8, 1952.

However, when hydrocephalus is noted in the neonatal period, when it is progressive and when the presence of subdural hematoma has been excluded, it is imperative that surgical care be considered. This does not mean that hydrocephalus can be corrected by surgical intervention, but a series of procedures that may offer a ray of hope are now under investigation. If hydrocephalus is to be corrected it must be done before extensive atrophy of the brain occurs from the increased pressure. The surgical techniques that have been devised include removal of the choroid plexus,[7] the Seton procedure[19,37] and various shunt operations, such as ventriculomastoidostomy[28] and ventriculo-ureterostomy.[27] In general, it is safe to say that the results of these techniques have been unsatisfactory but the outlook should not be wholly pessimistic since from these continued efforts it is hoped that some day a satisfactory method of management may be devised.

Respiratory System

Respiratory obstruction in the newborn infant may be associated with numerous lesions.[25] Large tumors about the nasopharynx, by virtue of their size, may prevent an adequate airway or prohibit feedings. These lesions may include ranula of the tongue, lymphangioma, hemangioma or cysts about the mouth or nasopharynx. Treatment in the individual case depends on the size, location and type of the lesion but tracheotomy may be necessary if respirations are disturbed. Congenital lesions that produce obstruction of the pharynx, larynx or trachea include hemangioma, fibroma, laryngeal polyp, cystic lesions of the larynx and congenital laryngeal relaxation (flabby larynx). In these instances tracheotomy may be a lifesaving procedure.

It is well to remember that, although tracheotomy in the newborn infant may be lifesaving, it is extremely difficult to manage tracheotomy tubes in children of this age. The tube must be cleaned at frequent intervals and nursing care day and night is absolutely essential. A small rubber catheter should be attached to an apparatus that provides gentle suction to aid the attending nurse in aspiration of the tube. A small plug of mucus is enough to obstruct the tube and cause suffocation. Too vigorous aspiration of tracheotomy tubes in the newborn child results in hemorrhage which may in turn produce crusts or flecks that obstruct the tube. An atmosphere of moist oxygen should be provided to aid in maintenance of liquid secretions. Efforts should be made to correct the primary difficulty as promptly as practical so the tube may be removed at the earliest possible date.

Infants who have laryngeal obstruction display an inspiratory type of stridor associated with marked retraction of the sternum, the suprasternal notch and even the supraclavicular area. Respiration may be extremely difficult and may be associated with a crowing sound. Cyanosis may or may not be present. This type of respiration persists regardless of the position in which the infant may be held. Roentgenologic examination of the thorax usually is negative. The laryngoscopist is of invaluable aid in the establishment of a definite diagnosis and the instigation of proper treatment of the primary lesion.

Choanal atresia[6,10] is a rare cause of respiratory distress in the newborn. The normal infant resists breathing through the mouth and when forced to do so takes feedings poorly. When the posterior nasopharynx is obstructed by an atretic membrane the infant is restless and respiratory embarrassment is most marked during feedings. The diagnosis of choanal atresia is confirmed by the absence of air passing through the nostrils and the demonstration, by inability to pass a small catheter through the nose, of a membrane across the nasopharynx. Surgical correction greatly relieves the air hunger of the infant and corrects the feeding problem.

Spontaneous pneumothorax[35,36] is an unusual condition in the neonatal period that may or may not be associated with known trauma at birth and may be the cause of severe respiratory difficulty. The degree of difficulty depends directly on the amount of air in the pleural space. In many cases spontaneous pneumothorax is so mild as to require no surgical intervention. Its diagnosis is established in an infant who has respiratory difficulty by absence of breath sounds over the affected side, accompanied by tympany to percussion. The heart and mediastinal structures are shifted away from the side in which the pneumothorax is located. This can be verified by roentgenogram of the thorax in which the collapsed lung may appear as a mass at the hilus and the normal markings of the lung are absent. Surgical measures are indicated immediately and are best carried out by introduction of a small S-shaped needle into the pleural space and maintenance of negative pressure by means of gentle suction. If the lung can be re-expanded and maintained in position, recovery should take place.

Closely associated with pneumothorax is pneumomediastinum[8] or the presence of free air in the mediastinal space. Considerable air must be present before symptoms are produced but if the pneumomediastinum is extensive it may produce pressure on the mediastinal structures, which results in respiratory difficulty. Aspiration of the air should be attempted in an effort to provide a free airway. If the air can be aspirated and its reaccumulation prevented, recovery should take place.

Congenital cysts of the lung are uncommon in the neonatal period and rarely produce extreme respiratory difficulty.[21,31] Cysts of the lung may be single or multiple, thin-walled or multiloculated, and about half of them contain fluid. They may produce respiratory difficulty by their size or they may become infected. Occasionally a cyst increases rapidly in size because of a ball-valve effect. Tension cysts produce rapidly progressive dyspnea that necessitates urgent surgical intervention. Roentgenographic examination of the thorax discloses the presence of a large thoracic lesion that obviously is displacing the other structures. On rare occasions it is extremely difficult to distinguish among pneumothorax, congenital cyst of the lung or diaphragmatic eventration by thoracic roentgenograms alone. If differentiation is difficult it may be necessary to give a small feeding of barium and watch for the presence of the intestinal pattern under the diaphragm. By this means diaphragmatic eventration and diaphragmatic hernia may be readily distinguished from pneumothorax, pneumomediastinum or congenital pulmonary cysts. Several recent articles have described the technique and indications for removal of congenital pulmonary cysts. Some of the cysts have been successfully removed in the first few days or weeks of life.[5,12]

Respiratory obstruction may result from abnormality in the great vessels of the heart. Gross and Neuhauser[17] have classified these lesions and described surgical techniques for their correction. Diagnosis of tracheal or esophageal compression by one of the so-called vascular rings is difficult and requires the help of roentgenoscopy and roentgenograms of the patient in various positions, in addition to careful auscultation of the heart. If the patient presents evidence of respiratory obstruction in the presence of a cardiac lesion and roentgenoscopic examination after ingestion of barium reveals compression of the esophagus, strong suspicion of a vascular abnormality should be entertained.

Congenital diaphragmatic hernia may produce gastrointestinal, respiratory or circulatory symptoms.[13] Diaphragmatic hernias are more common on the left side than on the right. They result from failure of the developing diaphragm to close the normal embryologic channels between the abdominal and pleural cavities. Defects in the pleuroperitoneal fold result in herniation of various abdominal viscera into the thoracic cavity. This results in collapse of the lung on the affected side. Infants who have large diaphragmatic hernias are cyanotic soon after birth. If the hernia is small, intestinal distention may be enough to result in collapse of the lung and cyanosis after feedings are started. Vomiting, although not always present, is common and begins soon after the first feeding. On physical examination it is noted that the side in which the hernia is located has decreased excursions and on careful auscultation intestinal sounds may be heard over the thorax. The heart and mediastinal structures are displaced by the hernia and the collapsed lung. Roentgenographic examination of the thorax after ingestion of barium establishes the diagnosis. Diaphragmatic hernia is a serious condition in the newborn infant; when it is accompanied by cyanosis, feeding difficulty or circulatory changes, surgical intervention is indicated. These infants should undergo operation as soon after birth as the diagnosis is established since the longer the operation is delayed the greater will be the tendency to gaseous distention in the gastrointestinal tract, which adds to the technical difficulty of operation. In the hands of experienced surgeons the results of corrective procedures have been extremely good.

Diaphragmatic eventration[2] is a congenital malformation, usually on the left side, characterized by thinning and marked elevation of the diaphragm so that it fails to function in respiration. This condition may produce dyspnea and cyanosis and is amenable to operation, which usually is not so urgent as in the case of diaphragmatic hernia. If the infant can be maintained in good condition by the use of supportive measures, operation may be delayed until the infant is considerably larger. On the other hand if the infant is having respiratory difficulty and maintenance by the use of oxygen and other supportive measures is difficult, surgical intervention should be carried out without delay.

Gastrointestinal System

Many lesions for which emergency surgical treatment is indicated are found in the gastrointestinal tract during the period just after birth.

Congenital atresia of the esophagus is commonly found at the level of the bifurcation of the trachea and is associated in a great majority of cases with a fistulous connection between the upper end of the distal part of the esophagus and the bifurcation of the trachea.[3,4,22,24,29,30] The diagnosis of atresia of the esophagus should be suspected in all infants who have difficult respiration, excessive mucus in the mouth and throat and attacks of cyanosis during the first few hours of life. Feeding results in immediate exaggeration of the respiratory distress. Once the condition is suspected, the insertion of a small soft rubber catheter into the esophagus confirms the presence of obstruction. A few cubic centimeters of radiopaque oil introduced through the catheter outlines the blind end of the esophagus and the fistula on the thoracic roentgenogram. In the presence of esophageal atresia without tracheo-esophageal fistula, no air is present in the gastrointestinal tract. Esophageal atresia is frequently associated with other abnormalities. The esophageal obstruction causes saliva to spill directly into the trachea, with resultant pneumonia or atelectasis. It is imperative that continuous or almost continuous aspiration of the esophageal pouch be carried out to prevent death from aspiration pneumonitis. When the diagnosis has been established, operation offers the only hope for recovery. The prognosis in esophageal atresia depends on a number of factors, including the amount of pneumonitis, the type of abnormality, the age and weight of the infant and the experience of the surgeon. In recently reported cases, the mortality rate has improved rapidly with increased experience in the management of these patients.[4,22]

Atresias of the gastrointestinal tract may occur at any location.[23] These lesions produce complete intestinal obstruction and are associated with vomiting that begins soon after birth. The rapidity of onset of vomiting is an indication of the location of the obstruction. Obstruction in the upper part of the gastrointestinal tract produces early vomiting with relatively little abdominal distention, while obstruction in the lower part produces marked abdominal distention, with vomiting that occurs later, after feedings are started. The vomiting of intestinal obstruction is projectile and persistent in contrast to the spitting or regurgitation commonly observed in infants who have poorly regulated feedings. Extreme dehydration and loss of weight are associated with any type of intestinal obstruction. In the presence of complete intestinal obstruction the infant passes little or no stool. The stool consists of dark meconium that fails to show cornified epithelial cells or lanugo hair on microscopic examination. Intestinal patterns soon develop on the abdominal wall and distention is progressive. If intestinal obstruction as the result of atresia or any other cause is suspected barium should not be given. A scout (preliminary survey) film of the abdomen confirms the presence of intestinal obstruction and frequently aids in the localization of the site of obstruction. Once the diagnosis of intestinal atresia is established efforts should be made to carry out surgical correction at the earliest possible moment. Infants withstand surgical procedures better during the first few hours after birth than during the next few days or weeks. If the obstruction is not relieved within a few days abdominal distention becomes marked, regulation of fluid and electrolytes is made difficult and perforation with generalized peritonitis and death results. The type of operation that is necessary depends on the findings at the time of exploration. More than one region of atresia may be present or other congenital anomalies may be found. The mortality rate after surgical intervention for intestinal atresia is high, perhaps 50 per cent, but many of the deaths result from conditions not related to the atresia.

Intestinal stenosis is an uncommon type of lesion of the gastrointestinal tract that may produce partial or complete intestinal obstruction. If obstruction is complete, the clinical picture cannot be distinguished from that of intestinal atresia. Partial intestinal obstruction as a result of congenital stenosis is rare in the newborn.

Intestinal obstruction in the newborn infant may be associated with numerous lesions, such as malrotation, intussusception,[32] volvulus, meconium ileus,[34] reduplications[15] or functional obstruction.[41] In such cases it is frequently difficult or impossible to distinguish between these lesions before operation. Little indication exists for delay in an effort to establish the exact type of obstruction since surgical treatment is indicated in any case.

Meconium ileus is a condition associated with cystic fibrosis of the pancreas, now named "mucoviscidosis" by some authors. The absence of pancreatic enzymes results in the meconium being extremely thick and tenacious, so that it cannot be passed through the gastrointestinal tract. This condition frequently is associated with volvulus, perforation or other lesions of the gastrointestinal tract. If the condition is suspected because of the familial incidence of the disease, a small specimen of stool obtained before operation may be suspended in a 5 per cent solution of pancreatin.[11] The tenacious meconium of patients who have pancreatic fibrosis rapidly dissolves in this solution. At the time of operation it may be necessary to use the method of Hiatt and Wilson[18] to relieve the obstruction. These observers were able to relieve the intestinal obstruction of meconium ileus by irrigating the obstructed portion of the bowel with isotonic solution of sodium chloride through a small catheter at the time of exploration. When the obstruction has been relieved the prognosis remains poor since the infants later die from severe pulmonary disease.

Anal atresia or imperforate anus is usually diagnosed by inspection; it causes progressive abdominal distention, vomiting, dehydration and absence of stools. This condition is frequently associated with congenital malformation of the genitourinary system; stool may pass into the bladder, vagina, perineum or ureters. Surgical correction must be carried out as soon as possible. An accurate diagnosis as to the location of the obstruction may be obtained by the technique of Wangensteen and Rice.[39] A small lead marker is taped over the anal dimple and a roentgenogram is made with the baby suspended by his feet. On rare occasions the connection between the rectum and the bladder, vagina or perineum may be sufficiently large to justify dilatation of this sinus tract so that it may serve as an anus until more definitive surgical treatment may be carried out. The decision as to the type of operative procedure must rest with the judgment of the surgeon in each case.

Hypertrophic pyloric stenosis is a common condition in newborn infants. It usually occurs in males and frequently is encountered in the firstborn child. It is associated with gradually increasing thickening of the pyloric sphincter and is characterized clinically by vomiting, a palpable tumor in the region of the duodenal bulb, presence of peristaltic waves, loss of weight, infrequent stools and disturbance in electrolytes if the condition remains uncorrected. Operation results in prompt improvement and should not be delayed beyond the time necessary for preparation.

Omphalocele or umbilical hernia is a congenital malformation characterized by herniation of abdominal contents into the umbilical cord.[26] The structure is covered by a translucent membrane of peritoneum and amniotic membrane. This covering may rupture at the time of delivery, which results in eventration and peritonitis. If the omphalocele is not covered within a few hours after birth it will dry out, become infected and rupture, with production of fatal peritonitis. Surgical correction should be attempted as soon after birth as possible. If the omphalocele is large and its contents cannot be returned to the abdominal cavity, skin should be approximated over the defect and secondary repair of the umbilical hernia done at a later date. Welch[40] has recommended the use of isografts to protect the thin-walled sac against infection. The mortality rate depends on the size of the omphalocele, the contents of the sac and the ease with which the contents may be returned to the abdominal cavity. Under ordinary circumstances a 50 per cent survival rate after operation should be expected.

Urinary System

Congenital malformations of the urinary system are quite common but rarely are an indication for emergency operation in the newborn.

Neoplasms

Neoplasms are rare in the newborn infant. Wilms' tumors,[16] teratomas,[14,33,38] neuroblastomas, medulloblastomas, sarcomas[1] and others have been described. If a neoplasm is found in infancy the same indications for surgical intervention exist as in later life.

PATIENT INSTRUCTION IN TUBERCULOSIS

Provision for individual patient instruction in the significance of asymptomatic tuberculous lesions of small extent, or indeed of all inactive or suspected tuberculosis, is a great need which has grown out of mass survey examinations. This can be provided only by giving both clinic physicians and nurses the time to give each patient the full explanation he deserves.—Howard M. Payne, M.D., Philip Enterline, and Julia Heuck, *The American Review of Tuberculosis,* November, 1952.

DERMATITIS FROM INDUSTRIAL OILS AND CHROMATES

RODNEY F. KENDALL, M.D.
Great Falls, Montana

THIS DISCUSSION of dermatitis caused by oils will be a brief review of what little information has appeared in medical literature, a discussion of some of the known causative factors, a smattering of histopathology of the lesions, a report of a few of my cases, especially as related to the railroad industry, and will pose a great many problems for future study.

In most of the standard textbooks there is a sentence to the effect that industrial dermatitis is an entity, followed by a list of chemicals and the type of eruption usually produced by each, a statement that avoidance of the irritant usually allows healing to take place and that re-exposure will cause recurrence of the eruption, but no fundamental information about the disease.

One of the first good accounts appeared about 1918, written about munition workers; the article might well have been written in 1951. It described the eruption exactly as we see it now, and gave about the same advice. Schwartz and Tulipan in "Occupational Diseases of the Skin" list petroleum, oils, tar, paraffins and halogen containing oils, cutting oils, sulphonated oils and some of the specific plant oils, tung, mustard, et cetera. There is no mention of the fundamental pathology. The first concise and easily understandable information comes in the Manual of Dermatology by Donald Pillsbury, printed for the use of the Army and Navy in 1942. In 1946 Klauder and Hardy produced a study of 532 cases of occupational dermatitis gleaned in 1,184 cases of skin diseases in industrial patients presenting claims for compensation, of which only 11 per cent were related to oils.

Our problem today, therefore, is to summarize the existing information on dermatitis due to oils. Solvents cause the largest number of cases of dermatitis which are due to a primary irritant. A primary irritant is a substance which is capable of producing a reaction in the skin of a majority of subjects who never have been previously exposed to the specific agent. The commonest irritants are the light petroleum solvents, especially type wash, mineral oil, kerosene and gasoline. Chlorinated hydrocarbons, turpentine, and solvents derived from coal tar follow closely but less frequently. The irritant action is directly proportional to the boiling range, and inversely proportional to the defatting action. Kerosene and solvents of low boiling range uniformly exert irritant action. Solvents containing compounds of chromium and sulfuric acid frequently cause eczematous reaction. Particularly we should mention the role of trauma in predisposing the dermatologic complications of injury. Apparently the skin can tolerate a certain exposure to these irritants, but when injured, cannot tolerate the usual exposure and provides a focus for the onset of dermatitis.

Of the eruptions usually seen in relation to contact with oil, the acneform types predominate. The first sign is the appearance of black dots or comedones in the follicles. A conical papule with a horny plug appears, followed by a tiny ring of inflammatory reaction and it soon turns into a pustule. Very little material can be expressed from the pustule, and healing is slow. Occasionally the pustule is large enough to be called a furuncle and when many are grouped in one area, the result may be incapacitating. The sites of predilection of these lesions are roughly located where there is heavy, coarse hair in an area exposed to friction: nape and sides of neck, forearms, anterior thighs, scrotum, calves. In my experience the reddish or sandy haired people are most susceptible but certain dark skinned workers have been seen. These, as I remember them, were handicapped by low intellect, and/or language difficulties.

In Montana we have another complicating factor that may not be seen in other areas. Most of our younger workers who are exposed to dirt and oils like to wear denim jeans. The popular style in Montana is the skin-tight cowboy jeans, which fit snuggly over the buttocks, thighs and calves. When these jeans are thoroughly impregnated with the offending oil, a mild folliculitis commonly appears in these areas. I have never seen it severe enough to be called furunculosis, but have

Read at the annual meeting of the Great Northern Railway Surgeon's Association, Glacier Park, Montana, June 29, 1951.

occasionally had to warn the patient to avoid grease, and to wear clean jeans.

Until O'Brien from Australia produced his classic article in the *Journal of Investigative Dermatology* in August, 1950, there had been no definitive study of the pathology of oil folliculitis. His study was directed chiefly to the etiology of poral closure, but inevitably his attention was called to the pilosebaceous follicles. He applied cotton pads moistened in kerosene to a test area on one side of the abdomen for fifteen minutes each day. The other side of the abdomen was treated in the same way except that the kerosene had been presaturated with anhydrous lanolin. After three days the test area showed the first elements of a rash composed of small clear superficial vesicles on a red base. After five more days during which only one more treatment was given, the rash became more florid, more infiltrated, and more like miliaria. Biopsies were taken from the test and control areas. In only one instance of thirty experiments was any rash produced on the control side; it was of a macular type. He made 600 serial sections from five biopsies. Three biopsies were from test areas, and two from control areas. The sections suggested that the solvent penetrated through the pilosebaceous opening causing an intense inflammatory reaction with internal and external infiltration of the follicle. Neutrophiles, monocytes and lymphocytes distended and infiltrated the neck of the follicle. Parakeratosis in the area surrounding the opening of the follicle occluded it. It seemed to show that the lipoid solvent caused intercellular edema and vesicle formation with subsequent infiltration and follicle plugging. However, the amount of irritation and reaction depends upon the properties of the chemical used. Kerosene which was saturated with anhydrous lanolin caused little or no reaction.

It is to be emphasized here that complicating factors of staphylococcic contamination, and low personal hygiene may prolong and aggravate the oil folliculitis. Other factors including improper attempts at treatment, previously existing dermatoses such as atopic or nummular eczema, psoriasis, lichen planus, acne vulgaris, or coexisting dermatitis venenata may confuse the issue.

O'Brien also experimented with soaping the normal skin with the ordinary brands of toilet soap. The histopathologic picture was the same as the areas treated with kerosene, but to a much less violent degree.

In summary we can say that persistent exposure to low boiling range solvents with a high defatting action, and over-exposure to the defatting action of any soap and particularly the alkaline detergents will cause a direct action upon the pilosebaceous apparatus with poral closure and folliculitis.

Treatment of the eruption, once it appears, should be directed in a logical fashion at the diametric opposite of the cause. The area should be cleansed of offending substances once, thoroughly, by a neutral or slightly acid detergent. Antibiotics may be used parenterally to combat the secondary infection that usually complicates the original eruption. In severe cases wet compresses with Burow's solution diluted 1:16, half saturated solution of boric acid, or even plain water, may be used. Removal of the patient from the offending substances, or vice versa, is necessary until the skin is well. Time is required to heal these follicular reactions—at least two and frequently four weeks.[1] In the hands of the dermatologist, small doses of x-ray therapy seem to shorten the period of disability, but x-ray must be given only by those familiar with its use, and with machines designed for superficial dermatologic therapy. In general, one should avoid applications of any ointment to the affected areas, though exceptions to this statement may occur.

When the patient returns to work, the offending agents must be avoided. Clean clothing, gloves, different detergents, and different solvents may make the entire difference between an efficient workman and one who is half-sick. In the workman whose cerebration is too slow to think through the problem, an attempt must be made to remove the offending substances completely from his use, or transfer must be made to another department.

In reporting my own experience with industrial dermatitis at Doctor Webb's request, particularly as far as the Great Northern Railway is concerned, I have had small material to report. Except for exposure to poison ivy, relatively few patients have come to my attention. Only three have been major problems. The *first,* a man with limited understanding of our language and ability to follow directions, as well as having a low level

(Continued on Page 92)

CORONARY INSUFFICIENCY

BURTIS J. MEARS, M.D.
Saint Paul, Minnesota

WHEN the cardiac muscle receives an inadequate supply of oxygen, pain and usually, but not always, electrocardiographic changes result, and the condition is called coronary insufficiency. This state of affairs may be either relative or absolute. The term "relative coronary insufficiency" is reserved for myocardial hypoxia occuring despite patent coronary arteries and is due to insufficient blood or deficient blood reaching the normal coronary arteries.

Shock, with its lowered blood pressure decreasing the coronary flow, and severe anemias, with the oxygen content of the blood lowered, cause only minor cardiac symptoms as compared to the severity of the primary condition. Hyperthyroidism, on the other hand, with its increased metabolic rate, hypertension, and elevated pulse rate, may actually cause a cardiac failure, and any resultant myocardial damage can be blamed chiefly on an insufficient supply of oxygen to the muscle fibers.

The presenting symptoms in paroxysmal tachycardia may be angina. The very rapid ventricular rhythm in paroxysmal tachycardia demands an increased coronary flow, but the coronary flow is actually decreased because of the shortened filling time of the nutrient arteries. As the tachycardia continues, anginal pain becomes a dominant symptom, and St-t changes in the electrocardiogram, typical of myocardial damage, occur.

These examples of relative coronary insufficiency are reversible when the primary disease is corrected.

In absolute coronary insufficiency the quality of the blood reaching the nutrient arteries is normal but the arteries are too narrow to deliver an adequate supply. Aside from the rare luetic aortitis causing narrowing of the coronary ostia, the chief cause of absolute coronary insufficiency is atherosclerosis.

Factors of etiological importance in the development of atherosclerosis are:

1. *Age.*—During the first year of life thickening of the intima of the coronary arteries is already apparent and this continues with age but causes little if any narrowing of the lumina.[8] Yellow lipoid deposits in the intima are found in 95 per cent of children over six months of age. These atheromatous patches increase in the first twenty years of life and in the following several decades decrease in size and number.[4] These anatomical changes appear to be reversible and could be due to the increased cholesterol intake and/or the poorly developed cholesterol metabolism in children. It is important to note that one third of the people over the age of eighty show only minimal arteriosclerosis. Therefore this disease must not be considered inevitable with advancing years.[3]

2. *Hypertension.*—As a general rule, the higher the arterial pressure the faster the atherosclerosis developes. Wherever the pressure is the highest in any given individual the more marked the degenerative changes will be. Thus in the arch of the aorta and in the vessels of the lower extremities degenerative changes are more marked. Atherosclerosis in the pulmonary circulation is rare until the pressure is raised as in emphysema, mitral stenosis and pulmonary fibrosis. When a cirrhotic liver raises the pressure in the portal systems, sclerosis of the portal veins is common. As a rule, therefore, all other factors being equal, the patient with hypertension will have more coronary sclerosis.

3. *Congenital or Inherited Tendency.*—At advanced age the hereditary element in coronary disease is lacking but when the condition is found before the age of fifty, a family history is usually obtainable.[13] In one-third of the adult population the right and left coronary arteries are of equal size and in this group coronary disease is minimal. In 50 per cent of the cases the right coronary artery is preponderant and in one-sixth of the cases the left artery is the larger, and it is in this latter group that we have the poorest prognosis in relation to coronary deaths. If the preponderant vessel is occluded the remaining hypoplastic artery is often incapable of compensating for the closed vessel.[16] The relative size of the coronary vessels is controlled by hereditary factors. Faulty

---

Read at the Annual Meeting of the Southern Minnesota Medical Association, Austin, Minnesota, September 8, 1952.

cholesterol metabolism is an etiological factor in possibly all cases of atherosclerosis and certainly is a defect in premature sclerosis and should be considered as a congenital defect.

4. *Sex.*—Coronary disease occurs five times as frequently in men as in women.[11] Under the age of forty the ratio of incidence is twenty men to one woman.[5] There must be some hormonal influence that protects the arteries in women against the invasion of cholesterol and the resulting atherosclerosis. Women do not develop the disease even during the recurring high chloesterol levels of pregnancy.[19]

5. *Constitutional Factors.*—The male who has a tendency towards female structure, namely wide hips, lack of body hair, and only moderate muscular development, seems to have a much lower incidence of coronary disease. In comparison the barrel chested hairy male with narrow hips, massive muscles, and thick forearms is prone to atherosclerosis. This man looks older than his chronological age.[12] Here again the relation of the androgenic to the estrogenic hormones would appear to be of vital importance. A relatively high ratio of androgenic hormones over the estrogens would appear to be conducive to atherosclerosis.

6. *Cholesterol Metabolism.*—There is a higher incidence of coronary disease wherever there is a disease causing hypercholesteremia, such as severe nephrosis, uncontrolled diabetes, hereditary xanthomatosis, myxedema, and Cushings syndrome. The incidence of atherosclerosis in experimental animals fed in high cholesterol diet is well known. Deaths due to atherosclerosis decreased in Sweden during the economic depression of 1930 and during the war years, and was attributed to the high starch low fat diet. Atherosclerosis is uncommon in patients in wasting diseases such as starvation in carcinomatosis. In a study entitled "Resorption of Arterial Atheromatosis Deposits in Wasting Disease," Wilens concludes: "It seems that their atherosclerotic deposits had been resorbed and their atherosclerosis had been a reversible process."[18] The importance of a high fat diet as an important etiological factor in atherosclerosis is still debatable but the stakes are high and the works and opinions of Gofman, Katz,[2] Boas and others, and the data of insurance companies[1,14] cannot be ignored.

The chief criticism of a low cholesterol diet in a given individual has been that some coronary patients show a low blood cholesterol, and if the cholesterolemia is high it often shows little or no reduction on a strict dietary regime. Goffman has stated that large lipo-protein molecules are found always in those patients with atherosclerosis and with weight reduction the number of these fat molecules decrease in the blood.[6]

Tobacco, alcohol, hard physical work, and the stress of living have not been proven to cause atherosclerosis. Physicians have long liked to think that the stress of their particular occupation has made them especially susceptible to early coronary disease. This has not been substantiated by recent studies.[10]

In the past few years the length of life after the diagnosis of coronary disease has increased because of improved treatment and earlier diagnosis. The chief symptom in the early coronary patient is often anxiety. To allay this anxiety, the doctor himself must be convinced that an optomistic outlook is justified.

The only treatment of value is prevention of the atherosclerosis before the artery becomes narrowed. Weight reduction is imperative and as the patient restricts his dietary intake he can be gradually trained to lower the fat content in his diet. Diabetics must be rigidly controlled with a rather liberal carbohydrate intake of at least 150 to 250 gm. and a low fat intake. No diabetic can be adequately controlled without two to three urine tests per day and the insulin dosage adjusted to these tests. Increased exercise in the controlled diabetic calls for less insulin, but exertion in the uncontrolled patient demands a larger dosage of insulin. The well-controlled diabetic contemplating a golf game or a hunting expedition should take less insulin and carry candy. There is an increase in statistical proof that adequate diabetic management decreases the incidence of arterial disease.[9,15,17]

Hypertension must be treated but great care must be exercised in the use of the new miracle drugs such as Hexamethomium, because the sudden dramatic lowering of the blood pressure and the ensuing prolonged sudden cardial ischemia may cause infarction. The patient may need a high systolic pressure to maintain adequate coronary flow. Although anxiety in itself does not cause or aggravate atherosclerosis, it is of importance if it elevates the blood pressure.

The activities required in the normal processes of daily living are all that are required for good health. Exercise over and above these minimal daily requirements in no way improve the general health. The coronary patient must be warned to limit his exercise below the threshold of anginal pain. If simple functions such as climbing stairs bring on pain, nitroglycerine should be used before this exercise.

The barrel chested male in the fifth decade of life who is becoming obese and carries a high diastolic pressure will often be found with a hemoglobin well over 100 per cent and a very low sedimentation rate. This is the patient that could well have a decrease in clotting time and be susceptible to intra-arterial thrombosis and should be encouraged to be a blood donor as often as possible. It could well be psychological, but these patients often admit to a sense of well being when the mild secondary polycythemia is relieved by phlebotomy.

There is no convincing proof that gallbladder disease or peptic ulcer occur more frequently in the coronary patient than in the otherwise normal individual. Gallbladder disfunction and distress from hyperacidity or ulcer seems to precipitate anginal attacks, and these two conditions must be remedied in coronary disease even if surgery is necessary.

The pain, usually nocturnal or following heavy meals, of diaphragmatic hernia must not be confused with coronary pain.

The only drugs of value in treating coronary insufficiency are sedatives and nitroglycerine. Each year a list of new drugs becomes available but are usually quickly discarded. Aminophyllin and papaverine are two of the most commonly used drugs and have no proven value except for the phenobarbital that is usually incorporated with these drugs. Nitroglycerine, freshly prepared, should be used liberally and the patient encouraged to rely on it at the slightest indication.

Conclusions

Coronary insufficiency is the result of narrowing of the coronary arteries because of atherosclerosis. The disease occurs as the patient ages and is apparently due to faulty cholesterol metabolism, the fault apparently being a congenital defect markedly affected by the androgen-estrogen ratio, and aggravated by hypertension and all diseases and dietary indiscretions causing hypercholesterolemia. Treatment consists of control of conditions causing hypercholesterolemia, rigid weight control, and relief of pain with nitroglycerine.

DISTURBANCES OF THE THYROID OTHER THAN HYPERTHYROIDISM

MARTIN A. NORDLAND, M.D. and MARTIN NORDLAND, M.D.

Minneapolis, Minnesota

INDICATIONS for the operative treatment of goiter, besides that of hyperfunction, are the removal of adenomata to improve the appearance of the neck, the relief of symptoms of tracheal compression caused by simple nodular goiters, as well as the prophylaxis and cure of malignancy and other pathological changes. Consideration should be given to the esthetic aspect of the disease raised by the patient, since a goiter which is unsightly is nearly always clinical as well. It very often involves the trachea and large blood vessels of the neck with harmful effects on the patient. Changes in size or contour of the thyroid gland causing cosmetic disturbances or pressure on the recurrent laryngeal nerves or those resulting in substernal and intrathoracic projections of gland tissue, are, as a rule, readily diagnosed and their treatment is just as readily indicated. In this type of case roentgenographic as well as laryngoscopic examination are of considerable importance in the preoperative management and in the surgical treatment of the disease. It has been estimated that in instances in which the goiter has produced symptoms of a mechanical nature, damage results to one or the other of the vocal cords in about 5 per cent of cases.

There are some conditions, namely, chronic thyroiditis of Riedel's struma, tuberculosis and sudden hemorrhage into a benign adenoma, which are often confused with malignant tumors of the thyroid. A correct preoperative diagnosis is most important in the surgical management of these patients.

In the differential diagnosis, the most noteworthy, although rare, is the so-called Riedel's struma, or woody thyroiditis. The etiology of this disease has been variously ascribed to tuberculosis, syphilis, and other types of chronic inflammation, but no convincing evidence of any of these factors has been presented. In this disease, the gland is so hard that its consistency has been described as stony or iron-like. However, its contour is smooth and rounded, the normal shape of the gland is retained, there is no hoarseness and there is little or no fixation of the gland to surrounding structures. There is no evidence of extension to regional nodes and distant organs. Malignant tumors are usually nodular and unilateral, they frequently metastasize early and soon involve the recurrent laryngeal nerves so that hoarseness and dyspnea are relatively common symptoms. The indications for surgical removal of the gland affected by woody thyroiditis consist mainly of pressure symptoms such as dyspnea and dysphagia. When surgery is undertaken for this disease it should, if possible, be limited to partial resection of the gland, since, as a rule, very little functioning gland tissue is left and myxedema may result. Late in the disease myxedema is common but this may be controlled satisfactorily by the oral administration of thyroid gland substance.

Tuberculosis of the thyroid, while extremely rare and of little clinical importance, is occasionally confused with malignancy. It has been noted that tuberculosis occurs frequently in association with increased functional activity of the gland already involved with hyperthyroidism. Whether the hypertrophic gland is rendered more susceptible to invasion by the bacillus of tuberculosis, or whether the infection stimulates the parenchyma to abnormal activity resulting in hyperthyroidism has not been determined. The disease is most frequently a part of a generalized tuberculosis or secondary to tuberculous infection elsewhere in the body. The result may either be a frank abscess formation or a chronically inflamed fibrotic mass. Microscopically, the latter type shows tubercles intra or interfollicularly. The surgical treatment is incision of the abscess or lobectomy, depending upon the condition encountered, and the prognosis is excellent.

In most cases of hemorrhage into a thyroid adenoma the history gives a correct diagnosis. Whether the patient had previously noted a goiter or not, the thyroid suddenly increases in size. This swelling, of a rapid onset, is associated with marked local tenderness and occasionally by symptoms of choking and pressure in the neck. Because the tumor following hemorrhage usually tends to subside over a period of a few days or weeks, it is readily differentiated from malignancy.

Malignant tumors of the thyroid are not extremely rare since the statistical studies show that from 3 to 17 per cent of all nodular growths in this gland are carcinoma. The greatest hope of cure of malignant lesions of the thyroid lies in the prophylactic removal of adenomas. The usually quoted textbook symptoms of cancer of the thyroid are really those of the end stages of the disease. A rapidly growing goiter with irregular lobulation distorting the usual symmetrical shape of the thyroid gland is rarely present until the condition is hopeless.

According to most investigators malignancy of the thyroid arises in about 90 per cent of the cases in a pre-existing nodular goiter usually in an individual in the fifth or sixth decade. As long as the growth remains inside the capsule, no symptoms are produced, so the exact time at which the malignancy begins cannot be determined. The goiterous enlargement is occasionally the only symptoms of which the patient is aware. Pressure on the recurrent laryngeal nerve or direct extension of the growth into the trachea results in hoarseness and cough, and if the esophagus is encroached upon, dysphagia is present. Hoarseness is a significant symptom since it usually means that the tumor has broken through the capsule and that the nerve is actually invaded or pressed upon. In non-malignant tumors of the neck, involvement of the recurrent laryngeal nerve is very rare.

The question of the possibility of carcinomatous lesions of the thyroid producing hyperthyroidism has not been completely settled although Pemberton states that this condition practically never takes place. When there is enlargement of the gland with hyperthyroidism, malignancy is rare, although in Pemberton's series, 87 per cent of the cases of malignancy were associated with benign nodules elsewhere in the gland. It is these benign adenomas which are most likely the cause of hyperthyroidism. In many instances operations are undertaken for supposedly benign adenomatous goiters only to find, by immediate microscopic examination or recurrence of the lesion at a later date, that the neoplastic change had already taken place. Needless to say, it is in these cases that are not diagnosed clinically that the best results may be expected. In early cases in which the carcinoma is confined within the capsule, removal of all of the growth without rupture of the capsule is sufficient. After malignancy has been diagnosed, the treatment of choice is radical resection, and, if this is impossible, irradiation alone or combined with surgical removal is strongly indicated. It may be stated that surgery alone in this condition is usually not justifiable even if the malignant lesion is entirely removed, although in many instances, radical resection has proved satisfactory. The latter is especially true of the papillary adeno-carcinomata, which grow slowly, and tend to remain encapsulated for a long time. In the more malignant types, radio-therapy certainly offers additional protection against the extension of the disease. Tracheotomy is frequently necessary, especially in the late stages of the disease, as a palliative measure.

The prognosis of carcinoma of the thyroid has been shown by Pemberton and Fricke and others to be as good as that of similar lesions of any other organ with the exception of the lip and the skin.

The management of the patient with hyperthyroidism does not come within the scope of this discussion. However, the clinician should keep in mind some practical facts concerning diagnosis and treatment. He should know that the rapid pulse comes early in hyperthyroidism and that it is more dependable as a diagnostic factor than the basal metabolic rate. He should remember that a high basal metabolic reading is not compatible with a slow or moderately elevated pulse. He must not forget that it is much safer to operate upon a patient with hyperthyroidism who is gaining weight than the one who is losing weight with the same basal metabolic reading. In other words, operation should only be attempted for the treatment of hyperthyroidism during a recession. He must be conscious of the fact that with the intelligent use of anti-thyroid drugs in the preparation of the patient, surgery is still the most valuable agent at hand, since it cures about 75 per cent of the patients with Grave's disease.

Roentgenotherapy has frequently been suggested in the treatment of hyperthyroidism. While it is admitted that in a large number of cases treated by x-ray, there is a gradual diminution in the basal metabolic rate and a general improvement of the patient, radiotherapeutic methods have several serious drawbacks. The dosage is difficult to determine. The favorable result in the beginning may, due to the cumulative action of the x-rays, eventually prove to be excessive. This treatment has none of the precision of the operative treatment. Further, radiotherapy is contraindicated in those cases of goiter, which sooner or later, come to operation. The inherent difficulties of an operation for exophthalmic goiter are increased to such an extent by preliminary x-ray treatment as to render the operation almost impossible. The adhesions after x-ray treatment are only to be compared in many cases to those produced by previous thyroidectomy in exophthalmic goiter and usually they are more marked. Further, a most important objection to x-ray treatment is the fact that visceral damage continues to advance while the gland is being treated and, in many instances, reaches a dangerous degree before it can be controlled.

In spite of the benefits of surgery in toxic goiter, recurrence of toxicity as well as persistence of symptoms occur in about 5 per cent of cases. The cause of recurrent symptoms following operation for exophthalmic goiter has not been fully explained. Various theories, as well as carefully conducted studies along this line, have been reported, but as yet no satisfactory reasons have been established as to why, in an occasional instance, recurrence of hyperthyroidism takes place at varying intervals following thyroidectomy. It is true that in many cases the cause of recurrence of the goiter can be definitely traced to incomplete removal of the gland, such as in hemithyroidectomy or in instances in which retrotracheal extensions are overlooked. Yet, there remains a certain definite group of patients in whom minimal amounts of gland tissue are preserved and return of symptoms is noted.

Classification of these recurrences, therefore, can readily be made on the basis of whether the previous removal of the gland was adequate or inadequate, and, of course, the proper treatment in the latter type of case is prophylaxis. This consists in a thorough removal of the gland, including the isthmus and also the pyramidal lobe, if present, leaving only a thin layer on the posterior capsule and taking care to locate and resect any retrotracheal extensions. This procedure will prevent most, but not all, recurrences, and it is in this latter type of case that one cannot attribute a return of the goiter to inadequate or incomplete surgery.

In only a few cases a partial return of some of the signs of hyperthyroidism is present and it is in these cases especially that therapeutic measures fail. In a certain group of cases, exophthalmos, frequently hardly noticeable preoperatively, becomes more and more progressive following removal of the gland so that permanent damage seems a likely factor in the production of these changes. The pathologic change responsible for this condition, as determined by Maffziger and Jones, is of mechanical origin, and, as described by them, is the result of pronounced swelling of the extra-ocular muscles to from three to eight times their normal size. They recommend, for these cases of progressive exophthalmos following thyroidectomy, removal of the roofs of the orbit through bilateral frontal bone flaps. X-ray treatment to the pituitary has proved most effective in the treatment of this condition.

Injury to the recurrent laryngeal nerves takes place most frequently in those patients in whom secondary operations are necessary. This is due to the fact that anatomical relations have become distorted through scar formation, resulting in displacement of the nerve into positions which are particularly susceptible to injury. This type of case again lends itself especially well to the performance of preliminary ligation of the inferior arteries and in the author's experience has given particularly gratifying results.

Postoperative hemorrhage which takes place in 1 or 2 per cent of even the most carefully done thyroidectomies, has occurred in our experience once. Good hemastases at time of surgery will prevent this complication.

CONTROL OF TUBERCULOSIS

Vast changes have taken place in our understanding of tuberculosis, the methods of its control and treatment, and the possibility of its ultimate eradication. As far back as 1937, Dr. Wade Frost demonstrated epidemiologically that this possibility could be made a reality even with the public health control methods then available, provided we intensified our efforts sufficiently. The goal is still distant, but new methods and discoveries give us courage to pursue it still more energetically.—Kendall Emerson, M.D., *Connecticut State Medical Journal,* May, 1952.

Laboratory Aids to Medical Practice

The Minnesota Society of Clinical Pathologists

FATAL ENTEROTOXIC REACTIONS CAUSED BY ANTIBIOTIC THERAPY

DURING the past year published reports have appeared concerning a hitherto unrecognized complication of antibiotic therapy, namely, a severe or even fatal micrococcal (staphylococcal) enterotoxemia that is caused by administration of terramycin or aureomycin. Practically all of these reports have appeared in France. This important sequela of therapy with antibiotics of broad spectrum was brought to the attention of the Minnesota Society of Clinical Pathologists by Dr. P. T. Sloss, a fellow in Pathology of the Mayo Foundation for Medical Education and Research, at a recent meeting of the Society. Because of the timeliness of Dr. Sloss's presentation and because of the widespread use of such antibiotics, together with the potential dangers involved in this little-known reaction, it was deemed advisable to present this information to the medical profession of Minnesota.

Mechanism

This serious complication of either prophylactic or therapeutic use of aureomycin and terramycin is not caused by hypersensitivity to the agents on the part of the patient but is produced by the effect of these antibiotics on normal fecal flora. Most of the fecal bacteria consist of organisms of the *Escherichia coli-aerogenes* group, together with groups represented by Bacteroides, Clostridium and Proteus. In minor numbers are found Pseudomonas, yeasts, enterococci and saprophytic micrococci.

When terramycin or aureomycin is given, a decrease in the total number of bacteria in the intestinal tract occurs during the first few hours; no great qualitative changes are noted, however. After the first few hours, important changes occur. *Escherichia coli* rapidly decreases in number and becomes practically absent by the fourth day after onset of antibiotic therapy. Organisms of the Proteus group, which are usually resistant to ordinary amounts of terramycin or aureomycin, increase in a reciprocal fashion. This increase becomes extremely rapid by the end of the fourth day, after which Proteus is predominant in the stool. Therefore, a period occurs, usually about the fourth day, when the total number of bacteria in the intestinal content is extremely small.

It is now well recognized that the incidence of strains of *Micrococcus pyogenes* (Staphylococcus) that are resistant to antibiotics is increasing; at present more than 30 per cent of all strains of this organism are resistant to terramycin and aureomycin. If a patient who is receiving one of these antibiotic agents happens to have such a resistant type of *Micrococcus pyogenes* in his intestine, the stage is set for possible disaster. At first the organism in question is present only in small numbers because its growth is retarded by means of competition for nutrition from the much greater numbers of other organisms present. However, on the fourth day *Escherichia coli* has almost completely disappeared and the Proteus group of organisms has not greatly increased. Therefore, the micrococci take advantage of this freedom from competition and multiply rapidly. Since about 40 per cent of strains of *Micrococcus pyogenes* produce quantities of potent enterotoxin, a characteristic syndrome may be produced.

Clinical Aspects and Diagnosis

The patient who harbors such an enterotoxic organism begins to vomit; extremely profuse watery diarrhea rapidly ensues followed by hyperthermia, a decrease in blood pressure, anuria and uremia. The term "choleriformic syndrome" has been applied to this condition because of its resemblance to cholera. Once this train of events appears, its consequences are grave unless it is quickly recognized and unless proper treatment is begun immediately.

This syndrome is a true bacteriologic emergency. When diarrhea appears in a patient who is receiving terramycin or aureomycin, the physician should immediately prepare a smear of the stool and stain it by the ordinary Gram's method. If this syndrome is present, the slide will exhibit myriads of gram-positive cocci as practically the only organisms present. If these organisms are found in anything but small numbers it is essential that administration of terramycin or aureomycin be stopped immediately. When cultures are made on blood-agar plates, pathogenic *Micrococcus pyogenes* will predominate and indeed may even appear in pure culture.

It should be stressed, however, that examination of the slide is sufficient to make the diagnosis and under no conditions should the physician await the outcome of cultures before the method of treatment is changed.

Treatment

If administration of terramycin or aureomycin is continued in the face of the syndrome just described, the bacterial conditions will remain the same and the patient will probably die. If administration of these antibiotic agents is discontinued as soon as the syndrome appears, the number of coliform organisms rapidly returns to normal and thus the growth of *Micrococcus pyogenes* is suppressed. About two-thirds of patients treated in this fashion recover quickly; the remainder die within a day or so.

However, the best treatment is to discontinue the administration of terramycin or aureomycin and begin use of erythromycin by mouth. Erythromycin is effective in the intestinal tract; it is suppressive to practically all strains of *Micrococcus pyogenes* and has little preventive effect on *Escherichia coli.*

Summary

A severe and frequently fatal micrococcal (staphylococcal) enterotoxemia may appear after use of terramycin or aureomycin because of emergence and rapid growth of enterotoxic strains of *Micrococcus pyogenes* (Staphylococcus) during that period when the number of other competitive intestinal organisms is at a minimum.

The toxemia is manifested by vomiting, intense diarrhea, shock, anuria and uremia. Prompt recognition of this "choleriformic syndrome" is necessary to save the life of the patient. Diagnosis is established by the finding of many gram-positive cocci in smears of the stool.

Treatment consists of withdrawal of terramycin and aureomycin and administration of erythromycin.

* * *

The material just presented is the first of a series of editorial reports to be given in Minnesota Medicine under the auspices of the Minnesota Society of Clinical Pathologists. Space for inclusion of these short reports has been kindly provided through the courtesy of the Editor of Minnesota Medicine, for which the Society is grateful.

The purpose of these reports is to bring to the attention of Minnesota physicians facts pertaining to the practice of laboratory medicine that may be of value when applied to the everyday problems which are encountered by the physician. Some of these facts will be new; others may be older but will be presented in such a form as to correlate material already known so that recognized facts may be better utilized in the practice of medicine.

All pathologists of Minnesota, like those elsewhere, are ready and willing at all times to render any aid they can to the clinician so that the scientific practice of medicine and ultimately the welfare and health of the patient may be furthered. The Minnesota Society of Clinical Pathologists is anxious to further the concept of mutual consultation between its members and those physicians who are on the firing line of medical practice. The pathologist will, of course, be aided in his attempt to keep abreast of medical progress by such contact. It is hoped that the clinician can also be helped by rubbing off a bit of the surprisingly heterogeneous body of information that clings to the mental periphery of the pathologist.

Clinicians are encouraged to buttonhole the pathologist in the corridors of the hospital or in his laboratory and ply him with questions that have any bearing, no matter how remote, on laboratory medicine. If the answer is not immediately forthcoming, the laboratory physician will make an attempt to discover a source of information. It must be remembered that the pathologist is a full-fledged physician and his specialized knowledge, if actively sought in a consultative way, may provide the answer to many a puzzling clinical enigma.

The Editorial Committee of the Minnesota Society of Clinical Pathologists, consisting of Dr. Arthur H. Wells of Duluth and Drs. Arthur H. Sanford and George G. Stilwell of Rochester, hopes that these reports will be of some interest and aid. Comments from any physician are extremely welcome and suggestions regarding material for future inclusion will be gratefully embraced. Communications may be addressed to any member of this Committee.

George G. Stilwell, *Chairman*

THE MEDICAL SCHOOL AND MEDICAL PRACTICE

THE ADDRESS by Dr. Charles G. Sheppard of Hutchinson entitled "The Medical School in Relation to Medical Practice in the State" which appears on page 23, was given at the staff meeting of the University Hospital on October 31, 1952, and is reprinted in this issue from the *Bulletin of the University Hospitals and Minnesota Medical Foundation* for October 31, 1952.

Dr. Sheppard is a well-known practitioner. He is a Minnesota graduate and at present is Speaker of the House of Delegates of the Minnesota State Medical Association. He has been on the governor's committee for the revision of commitment laws and has served on the tuberculosis committee of the Minnesota State Medical Association. He is also on the Board of Trustees of the Minnesota Medical Foundation and has maintained his interest in the Medical School.

Dr. Sheppard deserves a good deal of credit for bringing to the attention of the staff of the Medical School a number of phases of the education not only of physicians but of nurses and laboratory and x-ray technicians which he believes could be improved. His criticism is constructive and doubtless is shared by other physicians, both in the cities and in the rural districts. His suggestion that a committee for the Medical School be appointed to confer with the Committee on University Relations of our State Association seems a logical way of handling the questions raised. We recommend the reading and thoughtful consideration by our membership of Dr. Sheppard's address.

MINNESOTA'S NEEDS IN THE FIGHT AGAINST TUBERCULOSIS

THE ARTICLE by Dr. Francis F. Callahan which appears in this issue, provides some interesting factual material about the status of the tuberculosis problem in Minnesota.

The many workers in the field of tuberculosis during the past forty years in Minnesota and throughout the country are entitled to a great deal of credit for the remarkable reduction in mortality in the country generally and in Minnesota particularly during that period. The reduction in the number of reported cases of tuberculosis, however, has not been so striking. As Dr. E. R. Long stated in his Bell Lecture which appeared in our December issue, the number of cases among the negro population of Philadelphia has actually increased, according to the recent survey reported. Shifting population and x-ray surveys doubtless account for this.

Likewise, in Minnesota, there are certain areas which still offer a serious problem in tuberculosis control.

While it sounds like the beginning of the end of the fight to hear that several tuberculosis sanatoria in Minnesota have been closed and converted to other uses, there are certain factors, as Dr. Callahan brings out, that account for this apparent decrease in the patient load. In 1927, 200 beds for the tuberculous were added at the Veterans Hospital in Minneapolis, and recently 252 beds were provided at Anoka for the tuberculous inmates of mental hospitals of the state. In 1934, 100 beds were added to the State Sanatorium at Walker to provide for tuberculous Indians.

The migrating agricultural and industrial workers constitute a serious problem from the standpoint of the high incidence of tuberculosis in the group and the difficulty in detecting new cases and properly caring for them. Ramsey County, in contrast to some of the outlying areas, has had an insufficient number of beds in its sanatorium for many years.

One crying need for further facilities is the care of the recalcitrant patient with positive sputum who ignores proper sanitary measures to prevent the spread of the disease—the psychopath, alcoholic, tramp, and the like. What is needed, as Dr. Callahan indicates, is a 50-bed ward, preferably in connection with the Anoka sanatorium where this type of tuberculous patient can be forcibly quarantined.

The battle for the elimination of tuberculosis is progressing well, but it is far from being won.

It still requires all the means at our disposal to assure the continued reduction in the toll taken by this dread disease.

NEW COMMISSION ON ACCREDITATION OF HOSPITALS

FOR thirty-five years, the American College of Surgeons has classified the hospitals of the county according to standards set by the college. This undertaking has been instrumental in raising the quality of service rendered by the hospitals of Canada and the United States. The undertaking was, of course, entirely voluntary and has cost the College over $2,000,000.

It has been felt in various quarters for some time that the responsibility for setting standards and classifying hospitals should, in fairness, be shared by other organizations also vitally interested in hospital care.

At the December 6 meeting, Dr. Evarts A. Graham, chairman of the Board of Regents of the College of Surgeons, turned over the College's responsibility to Dr. Gunnar Gunderson, first chairman of the new joint commission representing the American College of Physicians, the American College of Surgeons, the American Hospital Association, the American Medical Association and the Canadian Hospital Association.

That the activity of the American College of Surgeons was effective in raising the quality of hospital care is shown by the fact that in 1918, the year after the institution of the program, only 12.9 per cent of the 692 hospitals surveyed were approved, while by 1951, 81.5 per cent of the 4,111 hospitals surveyed were approved.

Headquarters for the new Joint Commission on Accreditation of Hospitals will be at 660 North Rush Street, Chicago 11, Illinois. Dr. Edwin L. Crosby, former Director of Johns Hopkins Hospital, Baltimore, is Executive Director of the Commission.

EFFECT OF TV CRIME PROGRAMS ON CHILDREN

IN OUR ISSUE of November, 1951, under the heading "Wrestling No Longer a Sport," editorial mention was made of the deterioration that has taken place in the sport of wrestling. Attention was drawn to the fact that television makes these atrocious exhibitions available to the youth of our country and the obvious bad effect they must produce. We haven't noticed that the wrestling bouts have been discontinued as a result of the editorial.

The reproduction of wrestling matches on television constitute only a fraction of the presentations which have a deleterious effect on the youth of the country. Having acquired a television recently we, like all other owners, are in a position to evaluate the character of the programs presented—at least from five o'clock on. This marvelous invention in the field of communication has wonderful possibilities for the betterment of mankind. Man needs relaxation and amusement, and television can and does furnish both. But what about the effect of crime programs on the behavior and even the health of children?

A very impressive editorial appeared recently in the *Journal of the American Medical Association* under the title, "Influence of TV Crime Programs on Children's Health" (Sept. 6, 1952). Surveys have been made to determine the number of hours out of the twenty-four devoted to TV by children and the number of crime programs presented. Three and four hours a day spent in watching programs is not unusual. "During the week of May 24-30, 1952, six monitors tabulated 852 major crimes in addition to innumerable saloon brawls, sluggings, assaults and other 'minor' acts of violence. Their findings also include 167 murders, numerous robberies, jail breaks, murder conspiracies, false murder charges, attempted lynchings, dynamitings and an attempted rape in a crime Western for children." This was in California but doubtless applies to the rest of the country as well.

This is what we are feeding to our children in spite of the fact that we know how impressionable youth is, how prone to imitate, how emotionally unstable and how much their digestive and other functions are subject to mental reactions.

It is interesting to note that the use of TV in the field of education, which so far has only begun, is to be expanded. Television and, more particularly, colored television, has proven of value in medical education.

The transmission of TV crime programs is education of the wrong sort, and we can expect to pay for our negligence eventually. The television industry would do well to exert a much more stringent censure on the types of presentations voluntarily, before an aroused public opinion results in governmental regulation.

SISTER ELIZABETH KENNY

SISTER KENNY, justly famous for her treatment of poliomyelitis, died in Sydney, Australia, on November 30, 1952, at the age of sixty-six. She had suffered from Parkinson's disease and recently had a stroke involving her right side and speech center.

With only the medical training of a nurse, she hit upon the value of hot packs in the treatment of children attacked by polio in the bush country of Queensland, Australia. The discovery of the value of woolen blankets wrung out in boiling water in alleviating pain in the acute cases and preventing contractions was the outcome of her efforts to do something for these victims of what was to her at that time an undiagnosed disease.

Obtaining little recognition of her contribution in Australia, she came to America and was given the opportunity to demonstrate the value of her methods in the orthopedic department of the University of Minnesota. The medical staff became convinced of the value of her contribution, and the National Foundation of Infantile Paralysis contributed $500,000 in three years to promote study of her methods. Largely due to her inability to co-operate, a break was made in her relations with the Foundation and the Elizabeth Kenny Foundation was formed in Minneapolis with the help of public and private contributions.

Sister Kenny was a controversial personality. Her conception of the nature of poliomyelitis was not accepted by medical men, but that her emphasis on the value of hot packs and muscle re-education rendered a distinct contribution to the treatment of polio is the consensus of the medical profession.

COMMUNICABLE DISEASES

Last fall seven cases of typhoid fever occurred in Minnesota following a picnic at which food infected by a previously unknown typhoid carrier had been eaten. Such occurrences serve as reminders of how slight are the barriers between good health and the ever-threatening agents of communicable disease.

Minnesota Department of Health physicians point out that penicillin and other "miracle drugs" do not constitute a panacea for some of the most serious communicable diseases. Diphtheria, for instance, must still be combated by general immunization of the child population and by administering antitoxin when the disease occurs.

Smallpox is not amenable to any "wonder drug," and vaccination remains the one important defensive weapon against this disease.

ISOTOPE TRACER TECHNIQUE CITED AS VALUABLE MEDICAL ADJUNCT

As a diagnostic medium, the isotope tracer technique, using radioactive isotopes produced by the United States Atomic Energy Commission, has been hailed as one of the most valuable medical adjuncts since Roentgen's discovery of the x-ray.

A high accuracy in the determination of malignant and nonmalignant thyroid conditions was reported in an article in a recent issue of *Radiology,* published by the Radiological Society of North America and devoted to clinical radiology and allied sciences.

A report of experiences with the isotopes at the Harper Hospital, Detroit, was presented by K. E. Corrigan, Ph.D. and H. S. Hayden, Ph.D., both associated with the radiology department of the hospital.

The diseased thyroid gland is usually not a continuous organ; thyroid tissue is frequently found beyond the bounds of the capsule that surrounds the main gland. Local areas of malfunction are probably the most significant diagnostic problems. The Detroit scientists pointed out, "The thyroid is a highly unreliable organ, and in any state of malfunction its location and distribution are seldom those shown in the books on anatomy."

To aid in the diagnosis, radioactive iodine (I 131) was given by mouth on an empty stomach, excepting in cases where the patient was unable to swallow, in which event the isotope was administered intravenously. The radioactive material had a tendency to accumulate in diseased spots, which were then located by a Geiger counter in scanning studies covering the body.

The report said that 1,754 tracer studies were conducted up to the end of last March, with 107 diagnoses of a malignant growth of the thyroid.

"Of these," the scientists added, "eleven were totally unsuspected on clinical or any other grounds and were first reported as malignant by tracer technique."

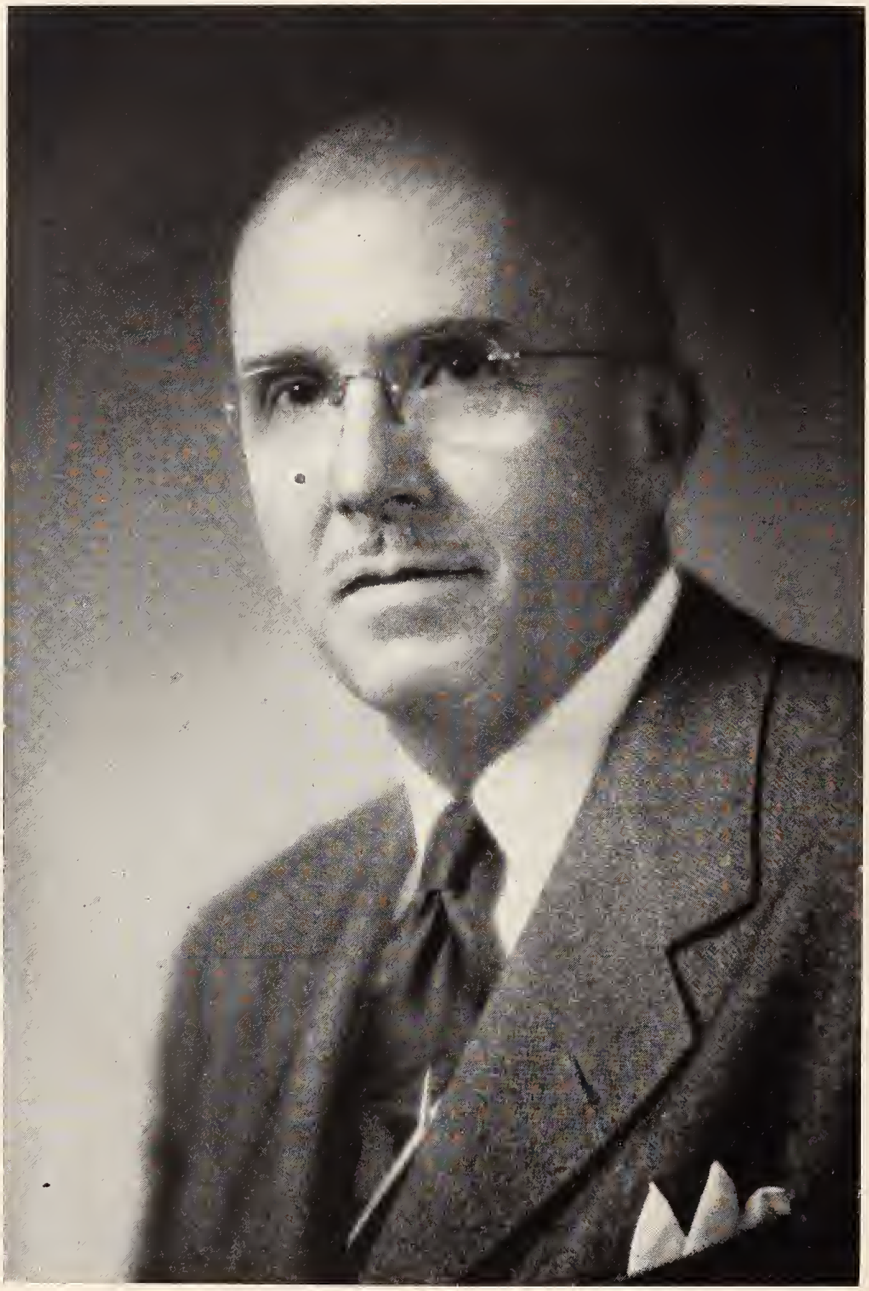
Four cases diagnosed malignant could not be demonstrated by subsequent microscopic examination of the tissue, although one later developed a metastasis (spread of a disease to elsewhere). In one case, a malignant lesion was found which had not been reported.

"In the other 151 operated cases, in which the original problem was to distinguish between malignant and nonmalignant thyroid disease prior to operation and the tracer report was negative for malignancy, no malignancy was found in any case," the report added.

The Detroit scientists also reported the use of a Geiger counter which had been built into a sterile probe. In one case, after the surgical removal of all of the thyroid tissue detectable by visual observation and feeling, the probe counter was inserted into the wound. It showed a strong localization of the radioactive iodine in an out-of-the-way place. A larger incision was made, and at the tip of the probe was found a dark colored ball of tissue.

This tissue on microscopic examination proved to be completely cancerous, the article added. The significance is that without the tracer technique, the second malignancy would not have been found, it was pointed out. "Since these apparently represented all the residual cancer present, the tracer obviously gave the patient some chance of prolonged life which he would not have had otherwise," the report said.

The Detroit scientists emphasized the importance of a thorough technique, adding that any inadequate procedure, especially one where a diagnosis is based on a single observation, can be dangerous and misleading.



Orwood J. Campbell, M.D.
President, Minnesota State Medical Association

President's Letter

A YEAR TO REMEMBER

The honor and privilege of becoming president of an organization is doubly significant and meaningful when that organization is commemorating its 100th anniversary. Such it is for me, as I assume the presidential duties of the Minnesota State Medical Association.

The organized medical profession of the state is, indeed, experiencing a memorable year. This is a year for remembering the marvelous medical advances which have been developed for the benefit of mankind during the past hundred years: the discovery of the "wonder drugs," the great decreases in communicable disease, the reduction of maternal and infant deaths, the great strides in public health, the improvements in treatment of mental illness, the reduction of surgical mortality accompanying the great expansion of the field of surgery, the development of improved methods and equipment, and the constant research into all medical fields so that continued progress will be assured in medicine's fight against one of man's most ruthless enemies, ill health.

The year 1953 is also a year for remembering individual contributions to the field of organized medicine: the fine work of the organization's outstanding workers; the years of service rendered by countless officers, councilors, committee chairmen, committee members; and the devotion of all association members who have faithfully supported the organization through the years.

But, as the centennial year begins, it is not only a time for looking back on past achievements, but a time for looking forward, a time to plan ahead for better service as a medical profession.

I am repeatedly impressed by the sacrifice of time and the real intelligence which busy practitioners have shown toward medicine's problems. I am proud that the Minnesota State Medical Association is comprised of such service-minded physicians who make up its list of officers, councilors, delegates, committees and members. I know that I, as president, can count on their willing co-operation and help in determining and carrying out Association policies.

I pledge myself to use my best thought and effort toward the betterment of the service which medicine can render the public, and toward a betterment of the understanding between the public and the great profession of which we are all a part.

COSTS AND INFLATION SLOW HILL-BURTON PROGRAM

The latest progress report on the Hill-Burton construction program shows that inflation and budget restrictions are rapidly slowing down the entire program. Since the program began six years ago, construction costs per bed increased, according to hospital authorities, about 50 per cent.

A résumé of the whole program states that approval has been given for 1,877 projects for federal grants totaling just over half a billion dollars. Of the 90,645 beds, about 44 per cent are already in operation, with the remainder under construction or in the planning states.

Appropriations for hospital construction have risen and fallen over the period of Hill-Burton's existence. For fiscal 1948 and 1949, the first full years of operation, appropriations made by Congress were for $75 million annually. Then, in 1950, Congress increased the maximum limit to $150 million, and voted the full amount. The next three years were given appropriations of $85 million, $82.5 million and $75 million, respectively.

Purposes Reviewed

A high percentage of funds has been given to relatively large institutions in urban areas. However, the program was primarily designed to give aid to the building of small hospitals and in rural areas. The Division of Hospital Facilities, Public Health Service, has this to say on the subject: "Although 57 per cent of the new projects are for facilities with fewer than 50 beds, only 25 per cent of the federal funds . . . (go) . . . to these smaller facilities. A little more than half of the federal money for new hospitals assists facilities with 100 or more beds. For additions or alterations, 82 per cent of federal funds is going to hospitals with 100 beds or more."

States Distribute Funds

According to the law under which Hill-Burton operates, funds are allocated to states for distribution. The responsibility of determining what projects get priority in fund allocation, is placed in the hands of the state hospital authority. Decision to leave it up to the states was based on a survey of hospital facilities and the willingness of local communities to make plans and raise money.

Although the emphasis is on larger, long-range jobs, it is noted that reduced grants are not immediately reflected in the administrative workload, which is expected to continue at about its present level for several years. At present, nineteen medical school-connected hospitals are grant-receivers.

REPUBLICAN VICTORY DEALS BLOW AT STATE MEDICINE

The second-guessers have waxed long and loud ever since the overwhelming Republican victory last November. As Eisenhower's new administration begins its arduous task of governing and administering, all eyes will be on Washington and its activities, and the observers will express themselves on activities, with great amounts of hindsight. Because hindsight is a less glamorous term than analysis, it is easy to understand why there is such a dearth of it, for, on the whole, it is a good deal safer and surer than wise foresight.

But a long sober look at the situation is usually highly worth the while for anyone who is vitally interested and affected by what goes on in his government. Doctors of the nation are no less interested and affected than any other conscientious American citizen, and have been so especially in the past few years.

And thus, the American Medical Association, in a post-election Secretary's letter, not to be outdone in second-guessing, sums up the Republican victory: "American voters went to the polls in record numbers last Tuesday and, in no uncertain terms, repudiated the Washington administration and everything it advocated, including compulsory health insurance."

The phrase, "everything it advocated," seems a little strong, when considered in the light of the fact that Eisenhower apparently does not intend nor does he even hint that he wants to clean out *all* New Deal policies and programs. He indicated in his campaign speeches that he was interested in improving most of them and in sharpening and polishing them to top efficiency.

But, the Republican victory certainly does bring with it a definite refutation of the compulsory health scheme which the Truman administration promulgated. The Secretary's letter states: "Doctors will no longer have to dance to the tune of the Ewing pipers, but can devote their full time and energy to a sound, constructive and unselfish program of better medical care for all the people—a program completely divorced from politics."

The letter goes on to quote the *Christian Science Monitor* which felt that "the President (Truman) totally underestimates the opposition to this program." The letter quotes the editorial more fully:

> "President Truman's effort to win support for compulsory health insurance by refraining from calling it compulsory is misleading. Any comprehensive government system of medical care insurance is bound to involve compulsion. It would be like the government's old-age insurance. Both employer and employe would be required to pay a tax, and it would be large. In Europe the taking of treatment prescribed in some cases is also compulsory."

Opposition Widespread

In its description of Truman's disbelief of opposition to the compulsory health insurance plan, the *Christian Science Monitor* continues:

> "He pictures it as consisting only of a medical lobby of a few men in the American Medical Association. On the contrary, the hostility to socialized medicine—which government health insurance implies—has long been dominant in and out of Congress."

Governors Polled

Governors of the forty-eight states were polled at the time of the Wagner-Murray-Dingell bill, and the paper reports:

> "In 1947 Senator H. Alexander Smith, chairman of a Senate committee holding hearings on a national health policy, wrote to the governors of the forty-eight states asking their views on two bills before Congress. One was the Wagner-Murray-Dingell bill providing for a national system of compulsory sickness insurance. Not a single governor recorded himself as favoring such a program. The legislatures of a number of states have memorialized Congress in opposition.
>
> "Many leading organizations have adopted resolutions against the proposition. These include the American Bar Association, the Chamber of Commerce of the United States, the American Farm Bureau Federation, the National Grange, the General Federation of Women's Clubs, the National Federation of Business and Professional Women's Clubs, the American Legion, and scores of others."

Summing up its feeling that this widespread opposition should be enough to make proponents realize its extreme unpopularity, the *Monitor* states: "The widespread antagonism to government-imposed health insurance is a natural reaction against a proposal which would involve great extension of government control, bureaucracy, deterioration in the quality of medical service, and invasion of the rights of the individual."

HEALTH INSURANCE HELD BY HALF OF UNITED STATES

Approximately 86 million Americans—well over half the country's population—has some form of health insurance. Some of it is sold by commercial insurers, but a big portion is administered by private associations linked to organizations of doctors and hospitals.

This information is seen in a recent issue of *U. S. News and World Report.* The survey, based on extensive research by the Federal Reserve Board, makes a general summary of the kinds of insurance held by Americans: "If you have hospital insurance only, you still must dig into your pocket to pay a surgeon for operating. If you have both kinds of this insurance, you will find a big part of your bills for expensive medical treatment is paid in advance."

Unpaid Bills Mount

The survey also showed that unpaid medical bills are owed by nearly one family in five. It states: "The average debt for each of these 10.2 million families is $105, or a total of more than 1 billion dollars. Doctors have a problem in collecting this considerable portion of their income."

In analyzing the composition of these groups of Americans, the survey points out:

> "Young families with children, mainly farmers or workers with small to moderate incomes, are most frequently in debt for medical care. Nearly one third of

those 15.9 million families in which the family head is less than 45 years old and children are under 18 owes medical bills. If you are among this big group of families, you also are among those most heavily in debt for medical care; of the 1.2 million families who owe doctors $200 or more, two thirds are among those with young children."

Whole Cost Not Seen

The study also notes that it cannot report the entire amounts that families spend for medical care:

> "Debts do not reflect all that families spend for medical care. When serious illness strikes, some have savings they spend before going in debt. Some, without savings, borrow from banks or other lenders, especially to meet hospital costs, which usually must be paid in advance. Millions have some form of private health insurance which, in major illness, pays a big part of the bill.
>
> "Of all money spent privately for medical care in the U. S., about $1 out of $9 remains as a debt to a doctor, hospital or pharmacist."

FDIC FURNISHES HEALTH COVERAGE

The Federal Deposit Insurance Corporation became the first government agency to give paid-up health plan coverage to its employes. According to a recent Washington Report on the Medical Sciences, FDIC has nearly 1,100 salaried workers, of whom some 400 are in Washington and the remainder scattered in the field from coast to coast.

The benefits are without cost to the employes. The report says that "they will receive benefits including up to seventy days hospital coverage and liberal in-hospital medical and surgical care, on an indemnity basis."

The plan also allows employes to choose whether they want payroll deductions to cover dependents. Rates are as follows:

> "A worker desiring coverage for a spouse, or a child under age nineteen, will pay $3.59 a month. For family coverage, regardless of size, the rate will be $5.27 monthly. Top surgical fee is $250. Fee allowed for each in-hospital visit by attending physician is $4, with maximum of twenty-three visits allowable in first nineteen days of hospitalization. Freedom of choice of doctor and hospital is guaranteed."

Although the FDIC is a federal agency, it is empowered to grant such a benefit program because it does not receive any funds from the U. S. Treasury. Its operating revenue comes from premiums levied on banks with insured deposits, hence it needs no Congressional law to authorize a program of this kind. There are other government agencies which are not Treasury-supported, and which may possibly wish to follow FDIC's lead. Among these is the Federal Reserve System.

It is also interesting to note that the signing of the FDIC contract with Health Service, Inc., was a precedent, and, according to the Washington Report, "may give impetus to the movement on Capitol Hill for enactment of legislation giving comparable health care coverage to all 2.5 million Federal workers, with Uncle Sam paying 50 per cent or more of the cost."

THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Building
Saint Paul 2, Minnesota

Julian F. DuBois, M.D., Secretary

MINNEAPOLIS PHYSICIAN SENTENCED TO FOUR YEARS IN FEDERAL PRISON

Re United States of America vs. Russell R. Heim

On November 10, 1952, Russell R. Heim, M.D., sixty-six years of age, with offices in the Wesley Temple Building, Minneapolis, and Coroner of Hennepin County, was sentenced to a term of four years in a Federal Penitentiary by the Hon. Gunnar H. Nordbye, Judge of the United States District Court at Minneapolis. Dr. Heim was found guilty by a jury on October 29, 1952, of 229 violations of the Harrison Narcotic Act.

The evidence at Dr. Heim's trial disclosed that Dr. Heim had issued 177 fictitious narcotic prescriptions for patients who did not receive the narcotic drugs. The evidence further showed that Dr. Heim sold the narcotic drugs to patients who were identified at the trial as known addicts, one of whom was employed by Dr. Heim in his office. Dr. Heim testified in his own behalf and admitted the writing of the prescriptions, but claimed that it was only a "technical" violation of the law and was done without any intent on Dr. Heim's part to wilfully violate the Harrison Narcotic Act. The jury refused to believe Dr. Heim and brought in a verdict of guilty on each one of the 229 counts in the indictment.

Dr. Heim was born at Plymouth, Indiana, and received his medical education at the University of Illinois, obtaining an M.D. degree in 1910. He was licensed in Minnesota in June, 1919, by reciprocity. Dr. Heim has been Coroner of Hennepin County since January, 1943. On November 22, 1952, Dr. Heim was served with a citation requiring him to show cause on February 13, 1953, why his license to practice medicine in Minnesota should not be revoked. Dr. Heim is serving his sentence at the Federal Penitentiary at Milan, Michigan.

Minnesota Academy of Medicine

Meeting of May 14, 1952

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, May 14, 1952. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p.m. by the President, Dr. O. H. Wangensteen.

There were fifty members and eleven guests present.

Minutes of the April meeting were read and approved.

Dr. Wangensteen announced the death of Dr. Charles D. Freeman which occurred since the last meeting and appointed Dr. Hynes and Dr. Hullsiek a committee to prepare a memorial to Dr. Freeman to be presented at the October meeting.

The Secretary announced that the Executive Committee had voted unanimously to transfer Dr. Clarence Dennis' name from the Active to the Honorary list and so recommended to the members present. Upon motion, it was so voted by the members.

Dr. Wallace Ritchie read a memorial to Dr. Alfred Adson and a motion was carried that it be placed on the records of the Academy and a copy sent to the family.

ALFRED W. ADSON

1887 - 1951

On November 12, 1951, one of the outstanding physicians of our time passed away at the age of sixty-four years.

Alfred Washington Adson was born in Terril, Iowa, on May 13, 1887. His father, a Norwegian sailor, had settled in Iowa and farmed in the early days of the nineteenth century. His education at the local high school and at the University of Nebraska gave early evidence of a keen, ambitious, constructive mind. Dr. Adson received his degree of Doctor of Medicine in the University of Pennsylvania in 1914, following which he received an appointment in general surgery at the Mayo Clinic. He rapidly advanced to the position of Professor of Neurosurgery of the Mayo Foundation, Graduate School, University of Minnesota, heading the section of neurosurgery from January 1921 to October 1946, when he became senior neurosurgeon.

Dr. Adson's contributions were outstanding, not only in the field of neurosurgery but also in the fields of organized medicine. In spite of an exacting life as a neurosurgeon, he felt an obligation to medicine in general, as indicated by the many positions he held in both state and national medical organizations.

One of the most important contributions to his medical colleagues and to the public was his unceasing efforts to advance the ideals and standards of medicine as evidenced by his loyal service to the Minnesota State Board of Medical Examiners from 1929 to 1951.

Neurosurgery was still an undeveloped field of surgery when Dr. Adson removed his first brain tumor on December 7, 1916, resulting in a complete cure of the patient.

The next thirty-five years witnessed a tremendous advance in neurosurgery. Dr. Adson's contributions to this advance were innumerable and important. He improved techniques, invented numerous instruments, and was a leader in the development of surgery of the sympathetic nervous system.

A good indication of a man's value to his world is by the number and calibre of the men he has influenced during his career. Three months before Dr. Adson's death, his former fellows honored him with a testimonial dinner. Approximately sixty-five out of a possible seventy-five men were present. The number returning is ample evidence of the respect and devotion that Dr. Adson inspired. Many of those present were already leaders in the specialty of neurosurgery.

Dr. Adson was admitted to membership in the Minnesota Academy of Medicine on April 13, 1938. His thesis was entitled: "Spina Bifida Cystica of the Pelvis; Diagnosis and Surgical Treatment."

His untimely end at the height of a great career was a shock to his many friends. Few men, however, are given the privilege to leave behind such a memory of indefatigable energy, creative instinct, stimulating leadership, and high character as has been left by Dr. Adson.

Wallace P. Ritchie

It was decided that the two papers of the evening, both on the subject of tuberculosis, be given first and then discussions of both papers follow.

PRELIMINARY REPORT ON THE PRESENT STATUS OF TUBERCULOSIS IN MINNESOTA

F. F. CALLAHAN, M.D.

Saint Paul, Minnesota

Dr. Callahan's paper appears on page 33 of this issue.

CHANGING TREATMENT OF TUBERCULOSIS

THOMAS J. KINSELLA, M.D.

Minneapolis, Minnesota

Dr. Kinsella's paper appears on page 29 of this issue.

DISCUSSION

Dr. S. M. White, Minneapolis: Dr. Callahan has emphasized the remarkable diminution in the death rate from tuberculosis in Minnesota. This does not give an over-all view of the situation for there seems to be no comparable diminution in the extant number of cases of the disease nor in the number of new cases reported per annum. I would like to know what is known about the situation with regard to morbidity in tuberculosis. Also, is the practitioner in Minnesota getting any better able to discover the disease early, aside from the mass surveys? And are the patients coming in any earlier than they did ten or twenty years ago?

Dr. Callahan: We do not have tuberculosis morbidity figures on a state-wide basis. We have some morbidity studies that have been carried on in many rural counties particularly in central and southern Minnesota. This work has continued for a number of years and we believe that the findings are reliable. The object of these studies has been to determine the effectiveness of the tuberculosis treatment and control program in the counties patterned after the method of establishing accredited counties worked out a number of years ago for the control and eradication of bovine tuberculosis.

A county, in order to be accredited in the human tuberculosis control program, must have a mortality rate of ten or less per 100,000 population per year and 90 per cent of all high school students in the county must show 10 per cent or less positive tuberculin reactors. In these accredited counties, the morbidity as well as the mortality rate is definitely on the decline. The Health Service at the University of Minnesota has been conducting tuberculosis morbidity studies of the student body for more than twenty years, and there has been a steady decline in the number of tuberculin reactors in this group. It appears that since the introduction of mass x-ray surveys, very few morbidity studies have been made in metropolitan areas.

The general practitioners in the state are not only diagnosing tuberculosis earlier than they did ten or twenty years ago but many of them are giving satisfactory follow-up post-sanatorium care to patients living in counties that do not belong to a sanatorium district.

Dr. Thomas Lowry, Minneapolis: There are many things one would like to talk about. I have enjoyed both of these papers immensely. I know Dr. Callahan will agree with me that in many parts of the country the tuberculosis situation is very, very different. Some of us have contacts at General Hospital where we see the itinerant population. We know even if we did get rid of tuberculosis in this area we would still have a constant influx or "hard core" of these patients from other parts of the country. As long as transportation and general migration of the population is as extensive as it is today, we are always going to have tuberculosis. I think another corollary of that is the question of benefit or lack of benefit of having been exposed to tuberculosis; is the man with a positive tuberculin test better fitted to go into areas with a high tuberculosis rate? The population of Minnesota is gradually becoming tuberculin negative and thus becoming highly susceptible to tuberculosis, and this brings up the question of vaccination with BCG of individuals having greater than average risk of exposure.

I would like to ask Dr. Kinsella how he feels about the treatment of minimal tuberculosis lesions which may regress on sanitarium treatment and arrive at a stable condition which we earlier would have felt was entirely satisfactory. Would he wish to take those out in order to avoid the chance of having them break down later?

Dr. R. H. Frost, Oak Terrace (by invitation): I have enjoyed very much these two fine papers on tuberculosis. Dr. Callahan properly laid stress on the striking decrease in our tuberculosis mortality rates during this century. As an example of this lowered death rate, it is estimated that if the mortality rates of 1900 had continued unchanged during the past fifty years, some 5 million more persons would have died of tuberculosis than actually did die of tuberculosis during this period—certainly a notable achievement. But I think we would be making a mistake if we were to center our attention too exclusively on the lowered mortality rates, and fail to realize that tuberculosis morbidity or attack rates—the actual number of patients requiring treatment for active tuberculosis—are not decreasing in any such degree, and in many metropolitan areas are actually increasing. The reasons for this are not entirely clear. Probably the most important reason is that we are going out and looking for tuberculosis by means of community-wide chest x-ray surveys and generally more effective case-finding programs.

In spite of the great progress that has been made, the fact remains that tuberculosis is still our most important public health problem. It still kills more people than all other communicable diseases combined, and more persons in the fifteen to thirty-four-year age group than any other pathologic entity. In a very real sense, we have only skimmed the cream of our tuberculosis control program—and we must now go to work to find tuberculosis and, having found it, treat it vigorously with the vastly improved techniques now available to us.

The therapy of tuberculosis is in a tremendously dynamic state. The things that have happened in the past few years are really amazing. For the first time we have truly effective antituberculosis drugs. To a very large extent we have abandoned collapse therapy as definitive treatment of pulmonary tuberculosis. Dr. Kinsella mentioned his collected, over-all mortality rates in pulmonary resections for tuberculosis. At Glen Lake Sanatorium in 1951, he (as our chief consultant in thoracic surgery) and one other thoracic surgeon did resections in 133 patients with three deaths. In retrospect, those three were probably not properly selected and would not be resected today. The initial results of these procedures are almost spectacularly good: a respectably low mortality, very few postoperative complications, good preservation of pulmonary function, a very high percentage of conversion of sputum and gastric cultures from positive to negative. Obviously much more time is going to be required in order to prove that these initially good results are going to hold up. I personally feel we are on the right track, and that for the first time in medical history we can treat tuberculosis in a truly definitive way. Certainly we are now restoring to health and good working capacity many tuberculous patients who until these recent years had nothing to look forward to except years of invalidism or death.

We have not started on intrapleural pneumothorax in the past two years. At Glen Lake Sanatorium practically the only type of collapse therapy now in use is a modest amount of pneumoperitoneum—and that primarily as a temporary "holding procedure" in relatively acute disease in the lower half of one or both lungs. Our best results in resectional surgery are obtained in lesions which, after adequate bed rest and chemotherapy, have become stationary and are no longer changing one way or the other. We still do some extrapleural thoracoplasties, but only as "tailoring" or space-filling operations in conjunction with, typically, an upper lobectomy. The incidence of such once-common postoperative complications as bronchopleural fistula and empyema is extremely low. However, it will probably be ten years before we can be sure that this is the proper way to treat pulmonary tuberculosis.

Dr. John F. Noble, Saint Paul: In the past eighteen months I have had the opportunity to study pulmonary tuberculous lesions removed surgically at the Ancker Hospital. Our material to date, however, is relatively small compared with Dr. Kinsella's experience. I agree with Dr. Frost and Dr. Kinsella both in their enthusiasm for this type of therapy, and I also agree that in order to properly evaluate it, a period of at least ten years must elapse.

Certain things about the excised material are interesting from a pathological standpoint. The lesions excised show an almost constant picture. The caseous areas are almost invariably surrounded by a dense fibrous zone. The picture is so constant that I am wondering whether the fibrosis is secondary to the chemotherapy. This, however, will be difficult to prove.

We have also learned that lesions diagnosed by planogram as cavities are frequently only potential cavities and are completely filled with caseous material. As far as I can determine they do not communicate with the bronchial tree at the time they are removed, although this potentiality must always be present. I cannot become too enthusiastic about the removal of minimal pulmonary lesions in children.

Dr. J. R. Aurelius, Saint Paul: I want to thank Dr. Callahan and Dr. Kinsella for presenting this subject. I feel very fortunate in having a ringside seat in this fast-changing picture of tuberculosis therapy. We radiologists seem to have the advantage of seeing it from all angles. Not very long ago we were seeing these patients pretty much put to bed and hoped for a cure through passive therapy but are now seeing the progress that is being made through active chemotherapy combined with surgery. Radiology has made some contribution to this in a way through the use of planograms. We think we see all there is in a chest when we get a good x-ray film of the chest but it is remarkable what additional findings the planogram will bring out. We are in a state of flux at present in the therapy of tuberculosis. It is a great period and it is very interesting to be on the sidelines and watch the passing show.

Dr. Callahan, in closing: In reply to Dr. Lowry's discussion on the itinerant patient, we believe that the tuberculous patient without state or county residence is one of the major roadblocks in the tuberculosis control program in the state and the problem is liable to increase before it gets better. Not only do patients with tuberculosis establish themselves in cities and counties known to have a good tuberculosis sanatorium, but on occasions county welfare board officials and health officers from other states have been known to advise patients to come to Minnesota for treatment. One welfare board actually paid a patient's railroad fare from a city in one of the west coast states to Minneapolis. On his arrival, he reported to the City Health Department and was committed as a public health menace.

In reply to Dr. Robb's question, histoplasmosis can produce isolated lung lesions that cannot be differentiated from active tuberculosis except by bacteriological studies. At a recent meeting of the Minnesota Trudeau Society, Dr. Corrin Hodgson reported three cases of isolated histoplasmosis in which the lesions had been resected. One of these cases had a rather large lung cavity that had the typical appearance of tuberculosis in the x-ray film. However, the usual case of histoplasmosis shows widespread calcified nodules in the lungs often associated with calcification of the hylar lymph nodes.

Wallace P. Ritchie, *Secretary*

ACCIDENTS LEAD AS KILLERS

Accidents cause more deaths in Minnesota in an average year than all communicable diseases, including tuberculosis; more than diabetes, arteriosclerosis, and nephritis combined; more than all adverse conditions of maternity and infancy. Accidents constitute the leading cause of death in all age groups up to thirty-five years.

More than 1,300 Minnesotans were killed in accidents during the first ten months of 1952. One-third of these deaths were caused by accidents in the home. One-third were motor vehicle accidents. One-third occurred in public places other than streets and highways, and in places of occupation.

During the period from January through October, 1952, home accidents outnumbered motor vehicle accidents, 489 to 452. During 1951, the last year for which complete figures are available, home accident deaths totalled 604, or approximately one for each 5,000 of our population.

For every accidental death, the National Safety Council estimates that 150 nonfatal accidents occur. Using the figures of the first ten months of 1952 as a basis, we may expect to finish this year with approximately 550 deaths and 82,500 disabling injuries *from home accidents alone.*

Falls are by far the leading causes of accidental death in homes. More than half the total of home accident deaths last year (358) were caused by falls. Other leading causes, in order of number of deaths caused, were burns, poisons—including gas poisoning—mechanical suffocation, and firearms.

Two main measures are recommended to cut down this appalling total—better housekeeping practices and more care in home situations. The "accident prone" individual is the biggest problem, because he constitutes a factor that is almost impossible to control. "He is impulsive. He is apt to act upon the spur of the moment. He is essentially a rebel. He cannot tolerate even self-discipline." Thus accidents are basically a mental health problem.

Prevention of accidents requires cooperation among home, school, community agencies, and health services. The public health nurse, who visits families in their homes, is in the most favorable position to help them prevent home accidents. She can do much to point out home hazards that might lead to accidents, and to assist in the correction of these conditions. She may also arrange for clinical studies of "accident prone" persons to determine ways of helping them and their families.—*Minnesota's Health,* December, 1952.

WHAT KILLS OUR YOUNG PEOPLE

Here are the leading causes of death, by ages, in Minnesota during 1951, for age groups under thirty-five:

Age in Years	*Total Deaths*	*Three Leading Causes of Death*
1-4	288	Accidents, 98; congenital malformations, 39; cancer, 38.
5-9	166	Accidents, 66; cancer, 25; diseases of central nervous system, 15.
10-14	130	Accidents, 59; cancer, 19; diseases of central nervous system, 9.
15-19	199	Accidents, 105; cancer, 15; diseases of central nervous system, 10.
20-34	722	Accidents, 274; cancer, 101; diseases of the heart, 49.

Virginia (Minn.) Health Bulletin, September, 1952.

DETECTION OF TUBERCULOSIS

Tuberculosis is notorious for the difficulty of detecting it in its early stages. By the time it is discovered, the disease usually has been transmitted to others. In view of this fact, no method of treatment will solve the TB problem in short order, although improved methods should help hasten the far-off day of eradication of tuberculosis. A good vaccine, superior to BCG—the one most widely used at present—would have greater potentialities for rapid control of tuberculosis than any method of treatment. There is no simple solution to the tuberculosis problem. The disease, because of its infectiousness, its present prevalence, its symptomless onset, its long duration, its tendency to recur even though once arrested, is one of the most complex and costly public health problems in the United States.—James E. Perkins, M.D., Annual Report of the NTA, Apr. 1, 1951, to March 31, 1952.

✦ Reports and Announcements ✦

INTERNATIONAL COLLEGE OF SURGEONS

Qualifying examinations for Fellowship in the United States Section of the International College of Surgeons will be held on the following dates in 1953: February 2 and 3, May 4 and 5, August 10 and 11, and November 2 and 3. The examinations will be given at the Cook County Graduate School of Medicine, and the Cook County Hospital. Applicants are requested to address communications to Harry A. Oberhelman, M.D., Secretary, Qualification and Examination Council, 1516 Lake Shore Drive, Chicago 10, Illinois.

WORLD MEDICAL ASSOCIATION AND PAN AMERICAN CONFERENCE

The first western Hemisphere Conference of the World Medical Association, of which Dr. Louis H. Bauer is Secretary General, will be held in conjunction with the Pan American Medical Conference, of which Dr. Jose Angel Bustamante of Havana is president, at Richmond, Virginia, April 23 to 25, 1953. The A. H. Robins, Inc., a pharmaceutical house of Richmond, is providing funds to cover the cost of the meeting. Scientific sessions will consist largely of panel discussions. The meeting will conclude with a dinner, Dr. Bauer presiding.

WORLD CONGRESS ON FERTILITY AND STERILITY

The First World Congress on Fertility and Sterility will be held May 25 to 31, 1953, at the Henry Hudson Hotel in New York City. This Congress is sponsored by the International Fertility Association with the cooperation of the American Society for the Study of Sterility.

Twenty-three scientific sessions will be held, including subjects dealing with socio-economic factors, psychosomatic aspects, and artificial insemination. The meetings will be conducted in English, French and Spanish, with the use of earphones and simultaneous translations, as in the United Nations meetings.

In addition to the scientific sessions, there will be medical round-table discussions, question and answer periods, scientific exhibits, and motion pictures.

It is anticipated that 1800 scientists from fifty-one countries will attend the Congress. Those who plan to attend should write as soon as possible to the Chairman of the Local Arrangements Committee, 1160 Fifth Avenue, New York 29, New York, for advance registration.

AWARD FOR OUTSTANDING RESEARCH IN THE FIELD OF INFERTILITY

The American Society for the Study of Sterility announces the opening of the 1953 contest for the most outstanding contribution to the subject of infertility and sterility. The winner will receive a cash award of one thousand dollars, and the essay will appear on the program of the 1953 meeting of the Society. Essays submitted in this competition must be received not later than March 1, 1953. For full particulars concerning requirements of this competition, address The American Society for the Study of Sterility, c/o Dr. Herbert H. Thomas, 920 South 19th Street, Birmingham, Alabama.

The author should append on a separate sheet of paper a short biographical sketch of himself and include a photograph to be used in the necessary publicity should he be the winner of the award.

MISSISSIPPI VALLEY MEDICAL SOCIETY CONTEST

The Thirteenth Annual Essay Contest of the Mississippi Valley Medical Society will be held in 1953. The Society will offer a cash prize of $100.00, a gold medal, and a certificate of award for the best unpublished essay on any subject of general medical interest (including medical economics and education) and practical value to the general practitioner of medicine. Certificates of merit may also be granted to the physicians whose essays are rated second and third best.

Contestants must be members of the American Medical Association who are residents and citizens of the United States. The winner will be invited to present his contribution before the Eighteenth Annual Meeting of the Mississippi Valley Medical Society to be held in Springfield, Illinois, September 23 to 25, 1953, the Society reserving the exclusive right to first publish the essay in its official publication— the *Mississippi Valley Medical Journal* (incorporating the *Radiologic Review*).

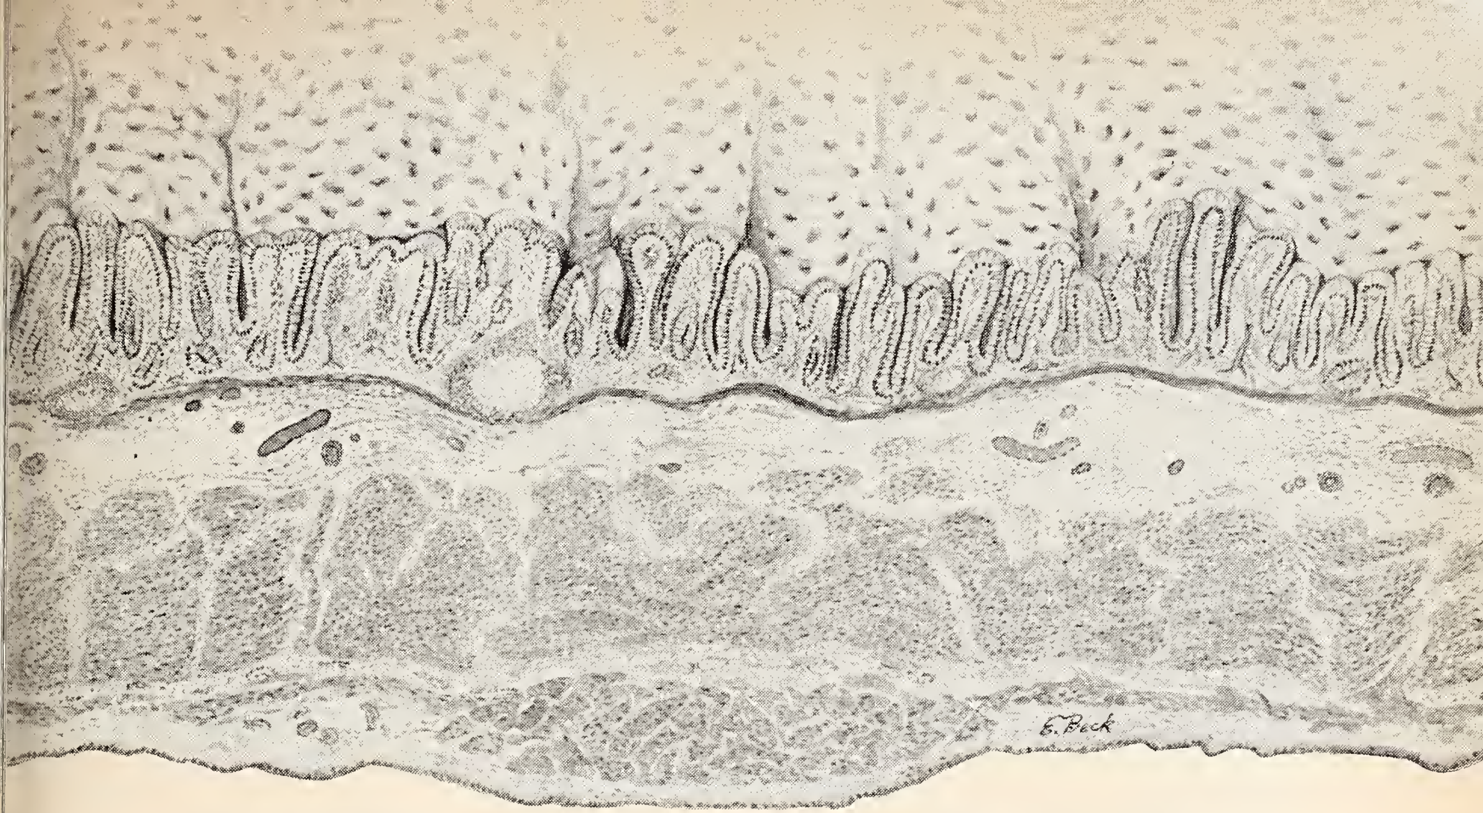
All contributions shall be typewritten in English, in manuscript form, submitted in five copies, not to exceed 5,000 words, and must be received not later than May 1, 1953. The winning essays in the 1952 contest appear in the January 1953 issue of the *Mississippi Valley Medical Journal.*

Further details may be secured from: Harold Swanberg, M.D., Secretary, Mississippi Valley Medical Society, 209-224 W.C.U. Building, Quincy, Illinois.

CONTINUATION COURSES

The University of Minnesota, in conjunction with the Minnesota Heart Association, will present a continuation course in *Cardiovascular Diseases* at the Center for continuation Study on February 12 to 14, 1953. Intended primarily for physicians engaged in general practice, the course will emphasize treatment of the more common cardiovascular disorders. Peripheral vascular disease will be thoroughly discussed. The program will also feature a clinical correlation session.

The guest faculty will include the eminent cardiologist, Dr. Arthur M. Master, Associate Professor of Clinical Medicine, Columbia University College of Physicians and Surgeons, New York City. Clinical and full-time members of the staff of the University of Minnesota



Normal peristaltic action results from activity of the muscle layers as they are gently distended by bulk within the intestine; mucosal irritants cause overactivity of the muscle layers resulting in hyperperistalsis or spasm.

Corrective Action of Metamucil® in Abnormal Physiology of Constipation

Abnormally prolonged colonic retention, whether in a spastic or an atonic colon, demands the greatest care to assure correction.

The mucosa does not require stimulating; hence, stimulating cathartics, "roughage" and other physical and chemical irritating measures, are today often considered irrational.

On the other hand, the muscularis does require a stimulus to initiate peristalsis. This physiologic stimulus is the mechanism by which bland distention of the colon establishes a reflex, with the muscularis at the terminus of the reflex arc.

Metamucil literally reeducates the sluggish and also the spastic colon. Taken with adequate amounts of water, Metamucil forms a smooth, hydrophilic colloid. As this colloidal mass passes through the large intestine, it exerts a gentle, distending pressure within the lumen, thus initiating the peristaltic reflex necessary for evacuation.

A program of Metamucil therapy helps to restore proper tone to the intestinal musculature, thereby establishing proper bowel habits.

Metamucil® is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%) as a dispersing agent. It is accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

ANNOUNCING

The Sixteenth Annual Meeting
of
THE NEW ORLEANS GRADUATE MEDICAL ASSEMBLY

Conference Headquarters – Municipal Auditorium
MARCH 2-5, 1953

GUEST SPEAKERS

J. Lamar Callaway, M.D., Durham, N. C.
Dermatology
A. H. Aaron, M.D., Buffalo, N. Y.
Gastroenterology
Herbert E. Schmitz, M.D., Chicago, Ill.
Gynecology
Carl V. Moore, M.D., St. Louis, Mo.
Hematology
Rudolph H. Kampmeier, M.D., Nashville, Tenn.
Internal Medicine
Henry A. Schroeder, M.D., St. Louis, Mo.
Internal Medicine
Guy L. Odom, M.D., Durham, N. C.
Neurosurgery
Andrew A. Marchetti, M.D., Washington, D. C.
Obstetrics
Harold F. Falls, M.D., Ann Arbor, Mich.
Ophthalmology
J. Vernon Luck, M.D., Los Angeles, Calif.
Orthopedic Surgery
G. Edward Tremble, M.D., Montreal, Can.
Otolaryngology
Arthur P. Stout, M.D., New York, N. Y.
Pathology
Waldo E. Nelson, M.D., Philadelphia, Pa.
Pediatrics
Edward B. D. Neuhauser, M.D., Boston, Mass.
Radiology
George Crile, Jr., M.D., Cleveland, Ohio
Surgery
Robert E. Gross, M.D., Boston, Mass.
Surgery
Charles W. Mayo, M.D., Rochester, Minn.
Surgery
Wyland F. Leadbetter, M.D., Boston, Mass.
Urology

Lectures, symposia, clinicopathologic conferences, round-table luncheons, surgical and medical procedures in color television, medical motion pictures and technical exhibits.
(All-inclusive registration fee—$20.00)

THE POSTCLINICAL TOUR TO EUROPE BY SHIP AND PLANE—ENGLAND, FRANCE, SWITZERLAND AND ITALY—MARCH 7-31

For information concerning the Assembly meeting and the tour write
Secretary, Room 103, 1430 Tulane Avenue, New Orleans 12, La.

Medical School and the Mayo Foundation will complete the faculty.

* * *

Under the auspices of the University of Minnesota and the Minnesota Cancer Society, a continuation course in *Cancer Detection for General Physicians* will be presented next February 5 to 7, 1953, at the Center for Continuation Study and the University Hospitals Cancer Detection Center. With the thought in mind that "each doctor's office can be a cancer detection center," registrants for the course will spend the major share of their time in the University's Cancer Detection Center, where they will participate directly in the diagnostic activities. Registration will be strictly limited in order that each registrant may obtain maximum benefit.

* * *

The University of Minnesota will present a continuation course in *Recent Advances in Diagnosis for Internists* at the Center for Continuation Study on February 16 to 18, 1953. Although intended primarily for specialists in internal medicine, the program will be of interest to many pediatricians and general physicians. This course will provide information concerning techniques which have been introduced or developed within the past five to ten years which have increased our knowledge of basic physiology and which are becoming or give promise of becoming standard diagnostic procedures. Recent developments in the fields of cardiology, respiratory disease, renal disease, hematology, gastro-enterology, and endocrinology will be emphasized.

Under the direction of Dr. C. J. Watson, Professor and Director of the Department of Medicine, an outstanding guest faculty has been assembled: Dr. Carl V. Moore, Professor, Department of Medicine, Washington University School of Medicine, St. Louis, Missouri; Dr. Thomas E. Machella, Assistant Professor, Department of Medicine, and Associate in Physiology, University of Pennsylvania School of Medicine, and Chief of Gastro-Intestinal Clinic, Hospital of the University of Pennsylvania, Philadelphia; Dr. Robert P. Grant, U. S. Public Health Service Hospital, Baltimore; and Dr. William W. Engstrom, Associate Professor, Department of Medicine, Marquette University School of Medicine, and Director, Metabolism Section, Milwaukee County Hospital. The remainder of the faculty will include clinical and full-time members of the staff of the University of Minnesota Medical School and the Mayo Foundation.

* * *

The University of Minnesota announces a continuation course in *Clinical Dietetics* which will be held at the Center for Continuation Study on March 2 to 4, 1953. During the two-and-a-half day session, recent advances in the field of clinical dietetics will be considered. In addition, a part of the course will deal with some problems in administrative dietetics. The program will be under the direction of Miss Gertrude I. Thomas, Director of Nutrition and Professor of Dietetics.

OPHTHALMOLOGY AND OTOLARYNGOLOGY CONVENTION

The annual spring convention in Ophthalmology and Otolaryngology will be held in Portland, Oregon, March 23 to 27, 1953. The program has been arranged by the Oregon Academy and the University of Oregon Medical School.

The meeting will be divided into two sections. Ophthalmology will be held Monday, Tuesday and Wednesday mornings (March 23, 24, 25) and Otolaryngology will be held Wednesday, Thursday and Friday afternoons (March 25, 26, 27).

Guest speakers will be Dr. Herman Burian, Associate Professor of Ophthalmology, State University of Iowa Medical School, Iowa City; Dr. Harold Scheie, Associate Professor of Ophthalmology, University of Pennsylvania Medical School, Philadelphia; Dr. Kenneth M. Day, Professor of Otology, University of Pittsburgh Medical School, Pittsburgh; Dr. Jerome A. Hilger, Clinical Assistant Professor of Otolaryngology, University of Minnesota Medical School, Minneapolis. Dr. Burian will deliver the fourth John E. Weeks Memorial Lecture in Ophthalmology.

A table will be available for the display of new instruments. Those wishing to display instruments are requested to notify David D. DeWeese, M.D., Secretary, 1216 S. W. Yamhill Street, Portland 5, Oregon.

INDUSTRIAL HEALTH CONFERENCE

New developments in methods for protecting and improving the health of the American worker and of insuring his safety will be reported by the nation's leading industrial doctors, dentists, nurses and hygienists at the 1953 National Industrial Health Conference to be held in Los Angeles, April 19-24, 1953.

Professional groups participating in the conference will be the American Conference of Government Industrial Hygienists, United States Navy Industrial Health Organization, American Association of Industrial Dentists, American Industrial Hygiene Association, Industrial Medical Association, and the American Association of Industrial Nurses.

This is the first time the six groups have ever scheduled their sessions together on the West Coast. Phenomenal increase in industrial activity in this area, particularly in Southern California, has finally attracted this important national conclave.

George F. Wilkins, M.D., medical director of New England Telephone and Telegraph Company and president-elect of the Industrial Medical Association, says that since employes in all industries and their families constitute the largest segment of the American population, the work of the conference actually concerns the health and economic well-being of the people of the United States as a whole. He believes that industry has no manpower to spare and a key theme that will recur repeatedly throughout this year's meeting will be keeping the industrial worker healthy and on the job.

WHERE ALCOHOLICS ACHIEVE INSPIRATION FOR RECOVERY

Where gracious living, a homelike atmosphere and understanding companionship contribute to successful rehabilitation.

200 acres on the shores of beautiful Lake Chisago

The methods of treatment used at the Hazelden Foundation are based on a true understanding of the problem of alcoholism. Among the founders of the nonprofit Hazelden Foundation are men who have recovered from alcoholism through the proved program of Alcoholics Anonymous and who know the problems of the alcoholic. All inquiries will be kept confidential.

ANNUAL CLINICAL CONFERENCE

CHICAGO MEDICAL SOCIETY

March 3, 4, 5, 6, 1953 • Palmer House, Chicago

THIRTY-FOUR HALF-HOUR LECTURES BY OUTSTANDING TEACHERS AND SPEAKERS on subjects of interest to both general practitioner and specialist.

FOUR PANELS ON TIMELY TOPICS.

DAILY TEACHING DEMONSTRATIONS.

- Neurology Clinic
- Dermatology Clinic
- Fracture Clinics
- Radiology
- Obstetric and Gynecology Clinic
- Cancer Clinic
- Fluid and Electrolyte Balance
- Rehabilitation Clinic

SCIENTIFIC EXHIBITS worthy of real study and helpful and time-saving TECHNICAL EXHIBITS.

The CHICAGO MEDICAL SOCIETY ANNUAL CLINICAL CONFERENCE should be a MUST on the calendar of every physician. Plan now to attend and make your reservation at the Palmer House.

Of General Interest

Dr. John Briggs, Saint Paul, was made an honorary member of the Sociedad Chilema de Tisiologia following his presentation of a paper before the society in Santiago, Chile, last summer.

* * *

The **Air Force Nurse Corps** needs 1,000 registered nurses to fill critical vacancies in Air Force Hospitals. Nurses, if accepted, will train at The School of Aviation Medicine at Gunter Air Force Base, Alabama, and will be given an opportunity to specialize in Pediatrics, Operating Room Techniques, Obstetrics, Neuropsychiatrics, and Anesthesia, or may fill the position of a staff nurse, head nurse, preventive medicine nurse, flight nurse or communicable disease nurse.

Second Lieutenants receive over $300 a month, educational opportunities and veterans benefits. Further information may be obtained by writing to the Chief Nurse Headquarters, First Air Force, Mitchel Air Force Base, New York.

* * *

Air Force Surgeon General **Harry G. Armstrong,** president of the Association of Military Surgeons, was host to the Surgeon General of the Korean Army and fifty military physicians from twenty nations at the annual association meeting in Washington, November 17 to 19.

Dr. Armstrong, a graduate of the University of South Dakota, interned at St. Luke's Hospital in Saint Paul and practiced in Minneapolis before he joined the air force.

* * *

Dr. A. C. Hilding, Duluth, spoke to the St. Louis County Medical Society on "Wanderings—Medical and Otherwise," at the meeting November 13, held at St. Luke's Hospital in Duluth.

* * *

Dr. Mario Fischer, St. Louis County health officer, was named a member of the community committee to investigate available facilities for housing and caring for mentally ill patients prior to the time their hearings are held in probate court.

* * *

Dr. R. M. Watson, who recently became associated with his father-in-law, **Dr. A. I. Arneson,** in the clinic at Morris, opened an office in Herman in November and plans to hold regular office hours there every morning.

* * *

Symbolizing another milestone in Minnesota's progress in the care of mentally ill patients with tuberculosis, the Burns Memorial building at Anoka was dedicated November 21, with **Dr. J. A. Myers** of the University of Minnesota as master of ceremonies.

The building was erected in tribute to **Dr. H. A. Burns,** who was tuberculosis control officer for state institutions seven years until his death in 1949.

Dr. Ralph Mahowald, Grand Forks, addressed the members of the Sacred Heart Men's Club on cancer, November 18.

* * *

Dr. Norman H. Baker, Fergus Falls, was elected president of the Red River Valley Council of the Boy Scouts of America at the annual Council meeting at Fargo, November 16. Dr. Baker has been active in Scout work for more than nine years and is chairman of the Wilderness Camps land development committee of the Council. **Dr. Charles Nelson,** of Fergus Falls, was elected an honorary vice president.

* * *

Dr. Al Emond, of Farmington, attended the fractures and surgery course at the Center for Continuation Study at the University of Minnesota, November 13 to 15.

* * *

Dr. Claude R. Hitchock, director of the Cancer Detection Center at the University of Minnesota, spoke on cancer research in South Saint Paul to a meeting of community members representing social, church and fraternal groups working with the cancer control program of the American Cancer society.

* * *

On the guest faculty of the second annual Regional Postgraduate Courses for Nebraska physicians, November 17 to 22, was **Dr. Corrin H. Hodgson,** of the Mayo Clinic.

* * *

Dr. D. S. Fleming of the division of tuberculosis, State Department of Health, spoke at the Steele County chest x-ray survey meeting held in Owatonna, November 12.

* * *

Dr. Theodore G. Martens, Rochester, consultant in ophthalmology at the Mayo Clinic, was the principal speaker at the annual dinner meeting of the Minnesota Society for Prevention of Blindness, held at Coffman Memorial Union at the University of Minnesota, November 14.

* * *

Dr. Clyde A. Undine, Minneapolis, attended the regional meeting of the American College of Physicians at Chicago, November 24.

* * *

Dr. Hamline Mattson of Minneapolis addressed the Rice County Medical Society, November 18, at Northfield on "Recurrence Factors in the Surgery of Inguinal Hernia."

* * *

Dr. Moses Barron, Minneapolis, was chairman of the city-wide diabetes detection drive which opened November 17, for a week. The drive was sponsored by the Twin Cities Diabetes Association, the Henne-

Who Finances a School Building

The School District first sells its bonds to a Municipal Bond dealer, like ourselves.

The Dealer then retails the bonds individually, in $1,000 denominations, to investors, such as yourself.

As the bonds mature, they are paid by the School District from the proceeds of a tax, levied over the life of the bonds, upon all of the taxable property in the School District. These taxes are a lien on the property prior to any other lien, including that of a first mortgage.

The interest the investor receives on his bonds is exempt from present Federal Income Taxes. We have a chart to show the advantage to you of this exemption.

We have such School Building Bonds for sale, at attractive interest rates, and invite your inquiry.

* * *

Dr. G. L. Griebie joined **Dr. A. M. Jensen** at the Brownton Clinic at Brownton, November 10. Dr. Griebie recently completed twenty-one months of military duty. Before being ordered to military duty he was associated with **Dr. J. D. Selmo** at Norwood.

* * *

Dr. Stanley R. Maxeiner, Jr., completed his surgical fellowship at Rochester, July 1, and received his Master of Science degree in Surgery. He is now serving with the First Marine Division in Korea.

Dr. Stanley R. Maxeiner, Sr., attended the Western Surgical Association meeting in December, at Houston, Texas, where he presented a paper on "Surgery of Regional Enteritis."

* * *

Speakers at the Minnesota Heart Association Fund Campaign meeting, November 22, were **Dr. Lewis Thomas**, research professor at the Variety Club Heart Hospital; **Dr. Grace M. Roth**, president of the Minnesota Heart Association, and **Dr. Harold S. Diehl**, dean of medical sciences at the University of Minnesota.

The Fund Drive for 1953, to begin in February, is annually sponsored by the Minnesota State Association of Life Underwriters.

Dr. John Briggs, chief of medicine at Ancker Hospital in Saint Paul and a regent in the American College of Chest Physicians, **Dr. Ezra V. Bridge**, superintendent of Mineral Springs, and **Dr. J. Arthur Meyers**, were member of a panel discussing Minnesota's tuberculosis problem and its treatment over WCCO-TV, November 16.

* * *

Dr. Arlie R. Barnes, Mayo Clinic heart specialist, resigned as chairman of the Clinic's Board of Governors in November because of illness. **Dr. Hugh R. Butt**, head of a section in medicine, was appointed to the unexpired term of Dr. Barnes. **Dr. Samuel F. Haines** was re-elected vice chairman of the Board and **Drs. Mandred W. Comfort** and **James T. Priestly** were reappointed to six-year terms.

* * *

After two years in the Navy Medical Corps, **Dr. Wallace R. Anderson** returned to his practice with the Austin Clinic. Dr. Anderson received his medical degree from the University of Minnesota in 1946 and did graduate work in pediatrics at the University of Minnesota before he joined the Austin Clinic in 1950.

* * *

Dr. Robert Meyer, Faribault, gave an illustrated talk on cancer to the members of the Faribault Exchange Club at their regular weekly noon-luncheon meeting, November 18.

* * *

Members of the Roseau Lions Club were guests of **Dr. D. O. Berge** and **Dr. G. S. Wheeler** at the reception room of their new clinic, November 13.

* * *

Dr. Reinald G. Johnson, St. Louis Park, was named Hennepin County coroner, November 24. Dr. Johnson has been in private practice for eight years. During World War II, he served in the Philippines with the Army Medical Corps.

* * *

Dr. F. N. Grose, Clarissa, and Mrs. Evelyn Hemming, Long Prairie, county nurse, were guest speakers following a half-day health exhibit in the Clarissa and rural schools. The Health Exhibit, including films, was sponsored by the State Department of Health and the Clarissa Parent Teachers Association.

* * *

Dr. B. J. Cronwell, Austin, Mower County chairman of the 1953 Heart Fund, attended the meeting on ways and means of financing the Heart Association Drive, held at the University of Minnesota, November 22.

* * *

Dr. Ralph K. Ghormley was elected the new president of the Mayo Clinic staff at a staff meeting, November 17. **Dr. Thomas J. Dry** was elected vice president and **Dr. Mark B. Coventry** was re-elected secretary. Councelors to the staff named were **Drs. L. P. Howett** and **D. M. Masson.**

* * *

Dr. Roger L. Kennedy, president, and **Dr. O. J.**

Campbell, president-elect, Minnesota State Medical Association, were named to the state committee for the Children's Home Society of Minnesota, November 24.

* * *

Mrs. John Hamlon, wife of **Dr. John S. Hamlon**, State Hospital, Fergus Falls, was a participant in the Pillsbury national baking contest at the Waldorf-Astoria in New York, December 8. She was one of three women in Minnesota eligible for the contest and won a prize of $1,000 for her cookie recipes.

* * *

A film on Norway, made on his recent trip there, was shown by **Dr. S. W. Giere**, Benson, November 30, at a meeting of the West Zion Luther League.

* * *

Dr. Norman A. Sterrie, Worthington, stressed the importance of immunization in the public schools over Station KWOA, November 23.

* * *

Dr. W. H. Sutherland sold his medical practice in Benson, November 22, to **Dr. Donald Holm** of Willmar. Dr. Sutherland is leaving his practice January 1, 1953 to take a six-month course in anesthesiology at the Veterans Hospital at Fort Snelling. Dr. Holm is a graduate of the University of Minnesota School of Medicine and has practiced in Willmar for the past two years.

* * *

Dr. E. E. Hartman, maternal-child health physician, Minneapolis Health Department, was granted a leave of absence January 18, to visit her father in Finland.

* * *

Dr. Dwaine Paal, of Currie, left November 20, for Baltimore, Maryland, to do postgraduate work at Johns Hopkins Hospital.

* * *

Concerning themselves with our increasing aged population, **Dr. Robert N. Barr**, deputy executive officer, Minnesota Department of Health, and **Dr. Helen Knutson,** director hospital service in the state, Minnesota Department of Health, spoke to a joint meeting of the County Public Health Nursing Advisory Board and Registered Nurses Club, held November 24 at New Ulm.

* * *

Dr. Robert W. Keyes, Pipestone, plans to practice in his home town as soon as he is released from service with the Army Medical Corps in February. Dr. Keyes was graduated from the University of Minnesota Medical School, interned at Chicago and was in practice at Hastings and Ely before entering the service.

* * *

Dr. Claude J. Ehrenberg, president of the Hennepin County Medical Society, was a member of the panel discussing the need of a new General Hospital at a Minneapolis Town Meeting, November 22.

* * *

One of twenty-three physicians selected to assist the committee on scientific exhibits for the American

Convalescence calls for High Protein and Knox Gelatine

Convalescence is associated with protein loss of serious magnitude, yet little is known of the fundamental nature of the loss.[1] Loss of nitrogen cannot be prevented; however, nitrogen balance can be maintained, wound healing enhanced, and convalescence shortened, by a high protein diet.[2]

Otherwise the patient uses his own "available" nitrogen stores to accomplish the healing defect.[3]

The patient "is better off before his nitrogen stores have been wasted than after. Surgeons have long noted that chronically debilitated patients are poor operative risks."[1] Decubitus ulcers heal quickly in heavily protein-fed patients.[4]

These facts are clear, as is also the fact that Knox Gelatine, which is pure protein, offers a useful method of supplementing the ordinary dietary protein.

Knox Gelatine is easy to digest, while its supplementary dietary nitrogen will furnish protein without other substances, especially salts of potassium which are retained during convalescence; without excess fat and carbohydrate, which are not needed especially; and without a food volume which may interfere with intake.

ADDRESS: REGISTRAR, 707 South Wood Street
Chicago 12, Illinois

Medical Association's 102nd annual meeting in New York, June 1 to 5, 1953, is **Dr. William H. Dearing, Jr.**, of Rochester.

* * *

Dr. Carleton Nelson of the Worthington Clinic, was named a diplomate of the American Board of Surgery in November. Dr. Nelson was graduated from the University of Minnesota and did his postgraduate work in surgery at the University of Minnesota and Minneapolis General Hospitals.

* * *

Among the speakers, sponsored by the Hennepin County Tuberculosis Association during the first week of the 1953 Christmas Seal Campaign, is **Dr. Sumner S. Cohen**, assistant medical director at Glen Lake Sanatorium.

* * *

Dr. Frederick J. Kottke, Minneapolis, was the principal speaker at a meeting of the Cambridge Community Club, held December 2. Dr. Kottke, on the medical staff of the University Hospitals, is the son of Mr. and Mrs. G. G. Kottke of Cambridge. He showed pictures and talked on his recent trip to Europe.

* * *

Governor John S. Battle of Virginia has written the governors of the other forty-seven states asking each of them to invite a seventy-five-year-old physician, a citizen of his state, to attend the first Western Hemisphere Conference of the World Medical Association to be held in Richmond, Virginia, April 23 to 25, 1953. The expense of the trip of the physicians from the states will be borne by the A. H. Robins Company of Richmond, which is celebrating its seventy-fifth anniversary. Travel and other expenses of delegates from the medical societies of the American republics as well as the invited physicians will also be borne by the A. H. Robins Company. Guests will be able to visit historic spots in Virginia including Williamsburg, as well as attend the meeting of the World Medical Association.

* * *

Dr. John W. James has become associated with **Dr. Ellery M. James** in the practice of anatomical and clinical pathology with offices at 657 Lowry Medical Arts Building and laboratory at St. Joseph's Hospital, Saint Paul. Dr. James is a diplomate of the American Board of Pathology.

* * *

While on a recent visit to Santiago, Chile, **Dr. Thomas B. Magath**, chairman of the section of clinical pathology and biochemistry at the Mayo Clinic, was made an honorary member of the medical faculty of the University of Chile, in recognition of his contributions to the field of parasitology.

* * *

Dr. Raymond G. Halvorson, formerly of Duluth, entered surgical practice at Rockford, Illinois, in December after leaving the United States Public Health Service. Dr. Halvorson, a 1945 graduate of Marquette University, Milwaukee, Wisconsin, interned at St. Mary's Hospital in Duluth and joined

the public health service in 1947 after serving with the United States Navy.

* * *

Dr. Kenneth E. Ahola joined **Dr. Robert T. Kelly** in practice at Nashwauk in November. Dr. Ahola is a graduate of the University of Minnesota Medical School where he was a classmate of Dr. Kelly. Both doctors interned at Minneapolis General Hospital.

* * *

At the annual meeting in November, the Blue Earth Valley Medical Association elected **Dr. Carl Krause,** of Fairmont, president, and **Dr. R. L. Parsons,** of Triumph-Monterey, vice president. **Dr. Herbert Boysen,** of Madelia, was re-elected secretary-treasurer.

* * *

Dr. George Kleifgen, of Park Rapids, resigned as village health officer, November 1.

* * *

Dr. Harvey Basinger was recently elected to the rank of associate in the International College of Surgeons. Dr. Basinger has been a member of the College of Surgeons since 1928.

* * *

Dr. R. J. Lindeman, of Paynesville, entered active military service in January. Dr. Lindeman reported to Gunter Air Force Base in Montgomery, Alabama, January 1.

* * *

Dr. Richard Jesse began medical practice in Truman in December. Dr. Jesse, who was recently discharged from the Army Medical Corps and will use the office and equipment of **Dr. M. J. Lester** until Dr. Lester is released from the Navy.

* * *

Dr. M. G. Fredricks, Duluth, was elected president of the Minnesota Dermatological Society at the annual meeting held November 26 at Ancker Hospital in Saint Paul. Dr. Fredricks is a staff member of the Duluth Clinic.

* * *

Dr. J. S. Blumenthal addressed the Ralph Pohl Post of the American Legion and Auxiliary on December 4, and gave his impressions of his recent trip to Europe.

* * *

Mayo Clinic staff members participating in the American Medical Association clinical session December 4, in Denver, Colorado, were: **Drs. E. V. Allen, C. F. Gastineau, F. J. Heck, R. L. Kennedy, L. C. Kolb, W. F. Kvale, G. B. Logan, A. M. Olsen, H. F. Polley, L. E. Prickman, T. W. Mears** and **H. J. Moersch.**

* * *

Among Minnesota's campaign leaders who heard Basil O'Connor of New York, president of the National Foundation for Infantile Paralysis, present cost statistics on polio care, December 5, in Saint Paul, were **Dr. Willis E. Dugan** of Minneapolis, chairman of the Minnesota March of Dimes, and **Dr. Walter Ramsey,** of Saint Paul, chairman of the Ramsey County chapter of the Foundation.

Dr. Robert Holmen, Saint Paul, spoke at the meeting of the Brotherhood of the Bethel Lutheran Church, December 5, at Willmar. Dr. Holman is a member of the Board of Charities of the Minnesota Conference of the Augustana Synod and has compiled, as a personal hobby, a history of all Lutheran bodies and synods in this country. He talked on his work of collecting and writing church history.

* * *

Dr. John D. McCarthy, resident pathologist at the University Hospitals, University of Minnesota, recently became engaged to Gladys Lucille Johnson, a senior nursing student at the University of Minnesota.

* * *

Dr. Milton Plucker, a graduate of Nebraska University, joined **Dr. M. I. Hauge** on the Clarkfield Clinic staff, Clarkfield, December 20.

* * *

Mayo Clinic staff members to attend the Western Surgical Association meeting, held at Houston, Texas, December 4 to 6, were **Drs. J. L. Bollman, V. S. Counseller, R. K. Ghormley, J. H. Grindlay, E. S. Judd, C. W. Mayo, and H. Waltman Walters.**

Dr. O. G. McDonald, member of the Duluth Clinic, was the principal speaker at the annual meeting of the Gogebic County (Michigan) Medical Society, December 2. Dr. McDonald spoke on, "Diseases of the Stomach—With Special Reference to the Ulcer Problem."

* * *

Minnesota chapters of the National Foundation for Infantile Paralysis will be in debt a total of $750,000 because of the 1952 epidemic. **Dr. Willis E. Dugan,** state chairman of the March of Dimes campaign, pointed out this fact in a talk before Ramsey County workers to discuss the financial situation, December 5.

* * *

Dr. J. A. Cosgriff, Sr., of Olivia, attended the American Medical Association meeting, held at Denver, Colorado, the week of December 8.

* * *

Dr. Philip S. Hench, of Rochester, attended the dedication of a public park in Havana, honoring the famed yellow fever workers—Drs. Walter Reed, Jesse Lazear and their associates—December 3. The park is located on the spot where Dr. Reed directed his experiments that led to the wiping out of yellow fever. Dr. Hench has done considerable research, beginning in 1939, on the real location of the yellow fever camp site in Cuba.

* * *

Dr. and Mrs. Earl Lowe, of South Saint Paul, returned recently from a two months' sojourn in Colorado Springs, Colorado. Dr. Lowe, who has been ill, has now resumed his practice.

* * *

Drs. Theodore Greenfield, and **H. E. Gaustad** of Cokato and **Dr. Gordon Watson** of Minneapolis returned December 2 from a vacation trip on which they served as members of a crew of six, sailing a boat in the region of the Bahama Islands, southeast of Florida.

* * *

Dr. Carleton Chapman, Associate Professor of Medicine, University of Minnesota, spoke at a pathological conference on heart disease, held at Redwood Falls in November for the medical staff of the Redwood Falls Municipal Hospital.

* * *

Dr. L. F. Van Veen joined **Drs. L. M. Evans** and **R. J. Cesnik** in their practice at Sauk Rapids, in December.

Dr. A. V. Stoesser, department of pediatrics, and **Dr. Norman Nelson,** department of internal medicine, University of Minnesota, presented the scientific program at the meeting of the Southwestern District Medical Society, December 6, held at Dickinson, North Dakota.

Dr. Stoesser spoke on, "Differential Diagnosis and Treatment of Respiratory Diseases in Children," and Dr. Nelson on, "Psychosomatic Medicine."

BLUE SHIELD NEWS

Among the benefit increases added to the Minnesota Blue Shield contract effective last October 1 was that of consultation. Since consultation with another physician is frequently an advantage to a seriously ill patient, this service as customarily used in medical practice was added to those already provided by the contract.

However, the possibility of abuse of the consultation privilege and the potential excessive cost, as previously experienced by one plan at least, required that certain safeguards regarding it also be placed in the contract. It was for these reasons consultation was limited to one service per subscriber per contract year at a cost of $10 per consultation. In addition, to assure that only serious conditions or vitally important issues constitute justifiable reason for consultation the words "bona fide and urgent need" were inserted in the consultation definition. And only to control any tendency to abuse the consultation privilege, the clause "the final determination of such need, however, to be made by Minnesota Medical Service, Inc.," were inserted in the contract.

It is of interest now, that during the first month of the operation of this contract provision, it is not clearly understood by physicians. This is evident from the receipt of three different types of ineligible consultation claims. One type clearly was not intended to be included as a consultation service and the other two types represent abuses, even though unintentional, for which safeguards were inserted in the contract.

First of these consists of daily attendance of the subscribers by a specialist other than the surgeon for the whole postoperative period when no serious medical complication is involved. Such claims are being received, are marked "Consultation," and specify that the medical specialist was called in to see the patient by the surgeon. In such cases, when another condition warrants it, a consultation fee is paid, or if serious medical complications are involved, routine in-hospital medical care fees are paid as provided by the contract.

In the second group are found those claims of doctors associated in practice calling in one another to see a case in the office or hospital when no serious hazard to the subscriber is involved. For instance, one partner called the other one in for an opinion about a submucous resection while the patient was at the office and the condition involved was a chronic one without the need for immediate surgery. Other similar consultations have involved chronic or recurrent non-hazardous conditions involving patients in the hospital.

And the third type of ineligible consultation is one in the home or office when a rather common condition is involved. Among the best examples of this is a home call to see an ambulatory patient about a commonplace gynecologic complaint. Neither the condition nor other circumstances involved fulfill the conditions regarding consultation services stipulated in the contract.

It is apparent from these facts that not only the purpose of adding consultation services to those previously provided, but also the limiting provisions and their reasons may not have been clearly understood by all members of the profession. Used properly consultation is of marked benefit to the subscriber as well as of both professional and financial advantage to the attending physician. Only by avoidance of abuses of the consultation privilege will it be possible in the future to increase the number of consultations per year at the fee for consultation. It is hoped that continuing experience with consultation services will warrant these increases in the future.

Blue Shield payment for surgical-medical care of Minnesota Medical Service, Incorporated, participant subscribers:

For 12 months of 1951	$3,095,213.00
For 10 months of 1952	3,070,475.00

Blue Cross payment for hospital care of Minnesota Hospital Service Association participant subscribers:

For 12 months of 1951	$11,312,390.00
For 10 months of 1952	10,426,444.00

The National Fund for Medical Education, with offices in New York, is launching a five million dollar industry-wide solicitation campaign in support of medical education in the United States.

Colby M. Chester, newly-appointed chairman of the fund's Committee of American Industry, will direct a nationwide organization to mobilize business concerns behind the nation's hard-pressed medical schools. Mr. Chester is honorary chairman of the board of General Foods Corporation.

The National Fund for Medical Education is a lay organization which is working in conjunction with the American Medical Education Foundation, founded by the American Medical Association two years ago. The AMEF's goal for 1953 is included in the amount.

The National Fund's Committee of American Industry, which will spearhead the campaign, will be composed of 100 ranking business leaders from every segment of industry. Their task will be to educate industry as to the critical needs of the medical schools. The committee contemplates solicitation of 25,000 American business concerns during 1953. Mr. Chester plans to appoint a vice-chairman, an advisory council, and division chairmen, who will direct the activities of more than fifty industrial committees. E. J. Ade, New York, has been appointed fund-raising director for the campaign.

TEXTBOOK OF SURGERY. H. F. Moseley, M.A., D.M., M.Ch.(Oxon), F.A.C.S., F.R.C.S. (Eng.), F.R.C.S. (C.). Assistant Professor of Surgery, McGill University; Associate Surgeon, Royal Victoria Hospital, Montreal, Canada. Foreword by G. Gavin Miller, M.D., C.M., M.Sc., F.R.C.S. (C), F.A.C.S., Chairman of the Surgical Department, McGill University; Surgeon-in-Chief, Royal Victoria Hospital, Montreal, Canada. 896 pages. Illus. Price $15.00, cloth. St. Louis: C. V. Mosby Co., 1952.

THE LITERATURE OF STREPTOMYCIN, 1944-1952. Selman A. Waksman. 553 pages. Price $5.00, cloth. New Brunswick, N. J.: Rutgers University Press, 1952.

DERMATOLOGY. Essentials of Diagnosis and Treatment. Marion B. Sulzberger, M.D. Professor and Chairman, Department of Dermatology and Syphilology, New York University Post-Graduate Medical School; Director of Dermatology and Syphilology, Skin and Cancer Unit and University Hospital, New York University-Bellevue Medical Center; Captain (MC) USNR., and Consultant Dermatologist to the Bureau of Medicine and Surgery, U. S. Navy; and Jack Wolf, M.D., Associate Professor of Clinical Dermatology and Syphilology, New York University Post-Graduate Medical School; Attending Dermatologist and Syphilologist, Skin and Cancer Unit and University Hospital, New York University-Bellevue Medical Center. 592 pages. Illus. Price $10.00, cloth. Chicago: Year Book Publishers, 1952.

SURGERY OF THE CHEST. By Julian Johnson, M.D., D.Sc.(Med.), Professor of Surgery, School of Medicine and Graduate School of Medicine, University of Pennsylvania, and Charles K. Kirby, M.D., Assistant Professor of Surgery, School of Medicine, University of Pennsylvania. Illustrations by Edna Hill. (Handbook of Operative Surgery). 387 pages. Price $9.00. Chicago: The Year Book Publishers, Inc., 1952.

The authors state in the preface, "Our objective, both in the text and in the illustrations, has been to present the step-by-step details of operative technic in as clear a manner as possible." This objective has been admirably achieved. The text is brief, incisive, and related largely to the explanation of well-executed line drawings, which convey most of the information in this book.

The first chapter deals briefly with surgical physiology of the thorax, diagnostic studies in thoracic surgical patients, pulmonary function tests, and pre-operative preparation. The second chapter deals with the management of chest injuries. Chapters 3 to 9 cover the various aspects of pulmonary surgery. The presentation of the pulmonary surgical anatomy is especially excellent. There is a chapter on surgery of the esophagus, one on surgery of heart and great vessels, and one devoted to surgery of pulmonary tuberculosis. The chapter on surgery of pulmonary tuberculosis is necessarily incomplete and contains a number of procedures that are now seldom done in many chest centers around the country. The final chapter is devoted to the repair of diaphragmatic hernias, the operative correction of pectus excavatum, and the excision of mediastinal tumors.

This book contains a lot of useful information presented in a clear-cut way and is well worth reading by both the thoracic specialist and the general surgeon who is faced with some thoracic surgical problem.

DIABETES GUIDE BOOK FOR PHYSICIANS. New York: The American Diabetes Association, Inc., 1952.

Figuring the optimum diet for a diabetic and furnishing him with easily understandable instructions as to his diet is not a simple matter for the physician. Often the services of a hospital dietitian seem almost essential.

This little booklet, however, put out by the American Diabetes Association, is primarily for use of the physician who has to figure out individual diets for his diabetic patients and instruct them as to their diets, without the aid of a dietitian. The booklet provides the simplest solution, that we know of, to this rather difficult job. We like it particularly because it provides lists of food exchanges and thus provides a great variety in the diet. We also like it because the sample diets contain substantial amounts of carbohydrate, a normal amount of protein and an amount of fat only slightly above that in a normal diet. The foods listed are all those contained in a normal diet and none is a special diabetic food.

By giving a copy of the booklet to the patient, the need of typewritten food lists is obviated. The booklet, however, is not complete enough to provide full instruction to the diabetic about his disease.

Copies of the Diabetes Guide Book may be obtained by physicians from the office of the American Diabetes Association, Inc., 11 West 42nd Street, New York 18, New York.

Incidentally, the American Diabetes Association publishes a bimonthly journal entitled *Diabetes* for the profession and a bimonthly publication entitled *Forecast* for the diabetic patient, both of which are very much worth while.

C.B.D.

DERMATITIS FROM INDUSTRIAL OILS AND CHROMATES

(Continued from Page 56)

of personal cleanliness, had folliculitis of the nape and dorsums of the hands and arms where he was exposed to oils and dirt while cleaning engines. This might have been avoided by personal care, but his shirts were rarely laundered, and his habit of wearing a greasy handkerchief around his neck contributed to the folliculitis. The last report showed healing of the areas, and I think we have taught him how to keep clean. The *second* and *third* cases are those of exposure to Nalco, a substance used in preventing corrosion in Diesels. It is composed of 72 per cent sodium chromate, 16 per cent sodium tetraborate, and sodium nitrate 12 per cent. Although only 0.6 oz. per gallon of water is used, a person allergic to the substance would have a violent reaction. The second and third patients were exposed to this substance in line of duty, and had repeated attacks of eczematous dermatitis (as opposed to the follicular dermatitis seen from oils). I applied patch tests to the forearm using 0.5 per cent Nalco and found strongly positive reactions in fourteen hours. Reactions to 0.5 per cent sodium chromate were also positive. Reactions to the other ingredients of Nalco were negative. Control tests were negative. The second patient had repeated attacks of eczema though he was not re-exposed to Nalco, but the patches of dermatitis were seen at the site of contact with chromium plated metal fasteners, eyelets on shoes, snaps on underwear, or at the site of contact with leather. The third patient changed occupations and had no recurrence. These two patients present clearcut cases of contact dermatitis to a specific chemical, in this instance sodium chromate, found in a special location in the railroad industry.

MEAD

MEAD JOHNSON & COMPANY
Evansville 21, Ind., U.S.A.

Dextri-Maltose
MEAD
D No 2 M

Especially indicated for premature infants. Contains 50 mg. ascorbic acid per ounce.

Dextri-Maltose
MEAD
D No 3 M

To aid in counteracting constipation. Contains 3% potassium bicarbonate.

designed with singleness of purpose

Designed and manufactured specifically for infant formulas, Dextri-Maltose® has an unequaled background of successful clinical use. Safety for your infant patients is assured by the dry form of this carbohydrate, meticulous laboratory control at all stages in its manufacture, and hermetically sealed, key-opening cans. Dextri-Maltose is palatable but not sweet; does not create a "sweet tooth" in infants.
Easily measured without spilling or waste and almost instantly soluble, Dextri-Maltose is convenient for the mother.

Chloromycetin®

THE ACHIEVEMENT OF THE MASTER CRAFTSMAN PROUDLY BEARS HIS NAME

I*nstrumentum ad artem medicae iuvandem.* "An instrument for aiding the art of medicine," indeed. For that is the motto proudly emblazoned on the Beck-Lee shield which is displayed on every *Cardi-all* instrument—and by its very meaning conveys the purpose of the *Cardi-all* to the medical profession.

Expressed another way: the *Cardi-all* makes it possible for any physician to afford a fine, sensitive electrocardiograph instrument that will provide heart records of high fidelity and precision.

CLINICALLY PRECISE—*Full frequency Galvomotor* assures accurate, dependable cardiograms.*

SIMPLE-TO-OPERATE—*Anyone with little or no experience in the operation of an electrocardiograph can operate the Cardi-all with less than an hour of training and make a complete record in a few minutes. An ingeniously designed recording unit permits change of paper roll in about 10 seconds.*

FULLY PORTABLE—*Completely loaded and including all accessories, this fine direct-writing electrocardiograph weighs only 27 pounds.*

AUTOMATICALLY CONTROLLED—*Stylus wandering due to line voltage variation virtually eliminated by means of specially designed circuits. The Cardi-all provides for an adequately stable iso-electric line for diagnostic purposes. Automatic self-grounding circuits plus the electronic separation of interfering voltages does away with the problem of AC interference.*

LOW IN COST—*Complete with all accessories, the Cardi-all is economically priced at only $495.*

HERE
LIES
PRINTER
JONES

If it's the printer's fault he ought to be shot.

But looking at it from another angle perhaps it points to a moral.

Maybe it is like a lot of businesses where all the stress is on selling . . . and the collection of accounts, so necessary for sound progress, takes a back seat.

Are your affairs run along these lines . . . with volume the goal and collections secondary? If it is then you need to change your policy.

TO CHANGE YOUR POLICY USE THE PROFESSIONAL CREDIT PROTECTIVE BUREAU

The Professional Credit Protective Bureau is collecting hundreds of past due accounts for dental and medical men.

The Professional Credit Protective Bureau is one collection organization that sees that the patient pays direct to the supplier of medical services. In other words you PAY THE COLLECTION ORGANIZATION AFTER YOUR PATIENT HAS PAID YOU and neither you nor the debtor is embarrassed.

More than 50 leading trade associations . . . including many medical and dental organizations . . . are using this service as part of their service to members.

It will pay you to investigate this tried and true system. Use the attached coupon.

Professional Credit Protective Bureau

Thank Yo

This is a personal note to all of you who have been so kind in expressing your confidence in this Agency. It is sincerely appreciated especially when we do try to merit the cooperation of your grand Association.

Since our special plan of disability insurance was first made available to the State membership, we have had many opportunities to test the worth of the plan itself as well as its administration, and believe that neither have been found wanting. Fortunately, the same can be said in connection with the experience of the thousands who are members of the other organizations listed which have endorsed and recommended the same special plan for their members. We believe that the length as well as the type of organizations in that list bears mute testimony to the value of this plan. It, in effect, vindicates the decision taken to make this available to your membership in 1947.

Your confidence in this Agency is a great source of encouragement.

HOW TO INCREASE THE PROTEIN INTAKE

without Patient Resistance

Patient resistance is rarely encountered when **H.P.S.** *Sixty* is prescribed to increase protein alimentation. This high protein supplement was carefully formulated to insure taste acceptance even when regular feedings are refused. Prepared with water or milk, it makes a universally acceptable beverage of bland taste, not unlike that of a milk shake.

60% PROTEIN in readily digested form

Consisting of intact proteins derived from milk, soybeans, and egg, **H.P.S.** *Sixty* provides 60 per cent protein and 27 per cent carbohydrate. Three servings prepared with milk provide 95 Gm. of readily digested, biologically complete protein. Prepared with water, 3 servings provide 77 Gm. of protein. **H.P.S.** *Sixty* is indicated whenever the protein intake must be sharply increased: pre- and postoperatively, to correct nitrogen loss following burns and hemorrhage, and in hepatitis, hepatic cirrhosis, malnutrition, pregnancy and lactation, and nephrosis.

H.P.S. *Sixty*®

Supplied in 1 lb. and 4 lb. tins

Therapeutic bile

overcomes stasis

"... the best bile salt to use ... would be the one that produced the most copious flow of secretion from the liver. ... In short, *hydro*choleresis would be advantageous, if achievable.

"It is. The preparation, dehydrocholic acid, commercially available as Decholin ... does considerably increase the volume output of a bile of relatively high water content and low viscosity. The drug is not a cholagogue, i.e., it does not promote evacuation of the gallbladder, but it is a good 'flusher'."*

Decholin®

dehydrocholic acid, Ames

*Hydro*choleresis with *Decholin* produces abundant, thin, free-flowing bile—"therapeutic bile." This flushes thickened bile, mucus plugs and debris from the biliary tract.

Decholin Tablets, 3¾ gr. (0.25 Gm.), bottles of 100, 500, 1000 and 5000.

Decholin Sodium (sodium dehydrocholate, *Ames*) 20% aqueous solution, ampuls of 3 cc., 5 cc., and 10 cc.

*Beckman, H.: Pharmacology in Clinical Practice, Philadelphia, W. B. Saunders Company, 1952, p. 361.

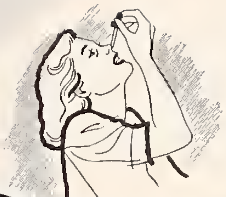
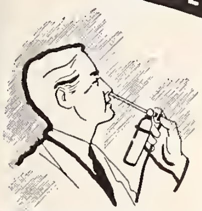
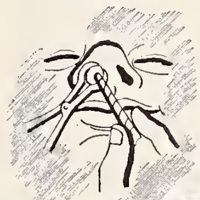
In Colds... Sinusitis



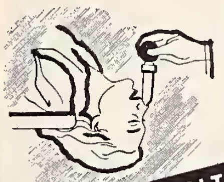
BY DROPPER...



SPRAY...



TAMPON...



DISPLACEMENT...

Neo-Synephrine hydrochloride is widely preferred as a decongestant in all stages of the common cold, sinusitis and allergic rhinitis because of its rapid and sustained action, virtual absence of sting, lack of appreciable interference with ciliary activity, virtual absence of congestive rebound and undiminished effectiveness on repeated use.

As to use of nose drops or sprays, I have about come to the conclusion that Neo-Synephrine is one of the best for all purposes.[1]

"... will produce exceedingly rapid and prolonged results."[2] "... action is sustained for two hours or more."[3]

THEY'D BE THREE-DEEP IN THE DINER

. . . all the patients who represent the 44 uses for short-acting NEMBUTAL

Case after case from the 593 published reports shows that adjusted doses of short-acting Nembutal can produce any desired degree of cerebral depression—from mild sedation to deep hypnosis.

And with only about half the dosage of many other barbiturates.

Your margin of safety is wide and the duration of effect short. And, since the drug is quickly and completely destroyed in the body, there is little tendency toward cumulative effect or barbiturate hangover.

If you'd like to expand your experience with short-acting Nembutal, write for your copy of the booklet, "*44 Clinical Uses for* Nembutal." Just address a card to Abbott Laboratories, North Chicago, Illinois.

Cordelia

AWARD WINNING BRASSIERES!

Cordelia surgical brassieres have won the Blue Ribbon for five consecutive years. Now, Cordelia has won BOTH the GOLD MEDAL and BLUE RIBBON AWARDS at the 1952 California State Fair Fashion Exhibit.

When she asks...

HERE ARE THE FACTS!

Most corrective, surgical and maternity brassiere problems have been scientifically solved by the staff of Physiospecialists at Cordelia of Hollywood.

THE GOLD MEDAL WINNER!

Each Cordelia brassiere is planned and made for easy, individual fittings by experts in local stores.

THE BLUE RIBBON WINNER!

Every Cordelia brassiere is a luxury in fashion fabrics — beautifully, youthfully designed. These are the facts judges took into consideration — then awarded *Cordelia the winner!*

Meat...

and the Therapeutic Value of Adequate Protein

Much evidence can be cited in favor of a high protein intake after surgery, trauma, infection, or burns. In supporting the many anabolic and defense mechanisms of the organism in physiologic stress,[1] high-quality protein—such as that of meat—assumes the status of an important therapeutic agent.[2]

Phagocytic activity,[3] formation of antibodies,[4] and rapid healing of wounds[5] are favorably affected by ample protein nutrition. Remission of peptic ulcer,[6] improved resistance to infectious disease,[4] and maintenance of plasma proteins after surgery[7] are other therapeutic effects attributed to an ample protein intake. In the management of ulcerative colitis, protein represents a primary need.[8] Recent advances in the treatment of extensive burns and of hepatic disease emphasize the value of high protein feedings.[9]

These experimental and clinical findings establish the therapeutic value of high protein intake.[10] To assure therapeutic protein adequacy, the dietary should provide a liberal margin of protein over normal requirements.

Meat is an important source of high-quality protein, containing essential as well as nonessential amino acids. In addition, it supplies significant amounts of B group vitamins and of iron, phosphorus, and other needed minerals.

a broad spectrum dietary supplement

When anorexia interferes with the intake of needed foods in adequate amounts, the resultant effect on the nutritional status of the patient is considerably more apt to involve deficiency in several nutrients than in one particular nutrient. In consequence, unpredictable subclinical deficiency states may arise, which can seriously impede convalescence. Hence when anorexia is present, it is good prophylactic therapy to prescribe a dietary supplement of broad nutrient spectrum, capable of improving the intake of virtually all indispensable nutrients.

The dietary supplement Ovaltine in milk enjoys long-established usage in clinical practice. As is evident from the appended table, it supplies notable amounts of virtually all nutrients known to take part in metabolism. Its biologically complete protein provides an abundance of all the essential amino acids. It is delightfully palatable, easily digested, bland, and well tolerated.

Ovaltine is available in two varieties, plain and chocolate flavored, giving choice according to preference. Serving for serving, both varieties are virtually alike in their wealth of nutrients.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

Number 2 of a series on the human meaning of great discoveries

THE DIFFICULTY OF KNOWING NOTHING

We may say that early man knew almost nothing. But nothing is just what early man could not know. The knowledge of nothing came hard and late in the progress of civilization. Plato and Aristotle, and even the great mathematician Euclid, calculated without a zero. With all that they knew, they did not know nothing. Bagdad of the Arabian Nights was the birthplace of the zero. The brawling bazaars of a great commercial city demanded swift accurate accounting, and the Arabian mathematician, al-Kwarizimi, met the need. Humanity's long journey out of darkness begins anew for each child opening his eyes to the light, seeking and discovering, finding answers to living needs. Science serves these needs from the moment of birth, even before birth.

How much does it cost, Doctor?

WHEN prescribing an infant feeding formula, you have doubtless often been asked by the mother, "Is it expensive?"

For most families—especially those with children—today's dollar doesn't stretch far. Hence the anxiety of mothers concerning cost.

BAKER'S
MODIFIED MILK
Powder form
Liquid form
For the Bottle-fed Baby
THE BAKER LABORATORIES

POWDER and LIQUID

Made from Grade A milk (U. S. Public Health Service Milk Code) which has been modified by replacement of the milk fat with animal and vegetable oils and by the addition of carbohydrates, vitamins and iron.

Sold at an extremely low price, Baker's provides a relatively high protein content (an ample supply of essential amino acids), four sugars, added iron and adequate amounts of vitamins A, D, thiamine, niacin and riboflavin. With Baker's, there's no need to prescribe additional vitamins (except C).

Yet the average cost of feeding most infants on Baker's is only about $1.50 per week. An economical answer to the question, "How much does it cost, doctor?"

NOTES: CONSTIPATION

WHAT BULK-PRODUCING PRODUCT IS EFFECTIVE FOR BOTH SIMPLE AND INTRACTABLE CASES?

Simple constipation

Many physicians report excellent results in the treatment of ordinary constipation with Hydrocil. Hydrocil absorbs liquids with unusual efficiency, creating 35 times its own weight of moist, lubricating bulk. Patients find Hydrocil pleasant and easy to take, too.

Intractable constipation

When mild bowel stimulation is desired in addition to effective bulk therapy, Hydrocil Fortified is recommended. To supplement its bulk-producing ingredients, Hydrocil Fortified contains acetphenolisatin, a newly-developed synthesis of the laxative principle in prunes.

This gentle, persuasive laxative has proved highly successful in correcting intractable constipation and preventing impactions after anorectal surgery.

How supplied

Hydrocil Fortified (blue label) and Hydrocil Regular (brown label) are provided in 4-oz. and 1-lb. canisters. A supply of Hydrocil for trial will be sent you upon written request. Address: Dept. M1, Fuller Pharmaceutical Company, 715 So. 10th St., Minneapolis 4, Minn.

Better Control for More Diabetics

Striking improvement is shown in the control of 1,281 carefully studied diabetic patients who were given NPH Iletin (Insulin, Lilly) for comparison with prior Insulin management. Of the 1,281 cases, 522 were classified as severe, brittle, or juvenile; 562 as moderate; and only 197 as mild. Although no single modification of Insulin can be expected to meet all the requirements for all patients, results with NPH Insulin appear to be as good as, or often far better than, those obtained by other means.

INSIDE THE BRITISH HEALTH PLAN

JAMES ROGERS FOX, M.D.
Minneapolis, Minnesota

PERHAPS it has not occurred to you that the practice of medicine in your own state is the optimum; that through all the trials and tribulations of patients, hospitals (or the lack of them), insurance, government forms and the like, your mode of practicing is not surpassed. Most of us have compared our brand of medicine and surgery here with other locales in the country and have come back to encourage some changes, but with the feeling that no other area is better. We are leaders in tuberculosis control, venereal disease control, child and maternity welfare and in the general approach to health. This point has been driven home to me more so since returning from Great Britain where I was fortunate enough to enter into their nationalized scheme. This arose from the fact that I was appointed a member of the visiting faculty at the University of Edinburgh which permitted me a living view of the teaching and specialties. On the other hand I was made a member of the British Medical Council Registry and as such saw patients on the basis of a general practitioner. This double situation permitted me the opportunity of studying and experiencing medicine in Britain with resultant impressions and comparisons with the United States. I shall limit my comments to those experiences in Britain, although my brief observations in other European countries suggested little better solutions of medical care.

To begin with, one cannot compare the United States and Britain. The traditions in Britain are more important to them than efficiency, and there is pride in this.

In addition there is one state the size of Minnesota, with about fifty million people. Moreover, politically and in the mechanisms of medicine their approach is quite different from ours. This is very interesting because the results are not too dissimilar. The general practitioner generally has his office in his home and sees patients there, in their homes, or at a nursing home. The last is analogous (though much less desirable and seldom over forty beds) to the private hospital here. There are operating and obstetrical suites, but no laboratory nor x-ray. These procedures must be obtained through specialists if the general physician cannot do them himself. In addition he must supply his own instruments, gowns and the like. The hospitals are ward in nature, such as our general hospitals and are limited to use by the specialist. Thus one easily can see that the gulf between the general physician and the specialist is broad. This has been increased since the adoption of the National Health Service, for the general practitioner is paid $2.38 per head per year for up to four thousand patients whereas the specialist is given a salary for his hospital work. In addition he receives some government paid consultations over and above any that he may receive privately. Do you believe that you could see four thousand patients as often as they desire through a year? Since the change in administration, this is being dropped to thirty-five hundred, but there is still a great deal to be desired. What has happened is that the niceties of medicine have increased to the pleasure of many, but the health problem of the nation including tuberculosis, housing, and public health measures has been overlooked—a vote is too important.

Many features of the socialization scheme are not so bad as we have been led to believe, whereas others are worse. The paper work is minimal.

After the numerous service, veterans administration, and insurance forms we have thrust upon us, I fully expected to be swamped; however, such was not the case. There is but one prescription form; the physician keeps records as he desires. The new administration has found it necessary to set up nuisances in order to abate certain abuses. There is a charge of fourteen cents for each prescription and no glasses can be obtained without a general physicians' referral. As you can guess the latter merely hampers the doctor. One very undesirable feature is that a physician who in his judgment deems it unnecessary to make a call, may be reported to the local board. For the most part a patient accepts his decision, but should the patient report him, the doctor must appear before this board which is composed of lay persons. The board decides whether the physician was out of line medically.

Beds are difficult to get, especially for tuberculosis patients. At the Royal Infirmary of Edinburgh there were 1,400 patients waiting admission to this 1,500-bed hospital. However, all emergency cases were cared for immediately. The tuberculosis rate is very high; in fact it had been mounting recently. Tuberculosis beds are under a central control, as are certain medications such as aureomycin. One must show good cause for the use of either for his patient. This would be a desirable situation were it not for the fact that the human equation enters in and favoritism can spoil this control. Many patients with moderately advanced tuberculosis are ambulatory for months because of insufficient staffed beds. Public health measures beyond those for tuberculosis, such as for venereal disease, child and maternal welfare, immunization, water and milk sanitation and the like are literally a generation or more behind us, and yet the niceties are being made available. The physician does not have interference with his handling of patients beyond what I have mentioned. Patients select their doctor by signing the registry of the physician they desire until his maximum enrollment has been reached. Conceivably he could see others if they would pay directly, but where could he find the time? The physicians in general are not happy with this centralization of medicine, but now they are being paid for their endeavor. The specialist, who previously donated his time to the hospital, now receives a very adequate salary for that time in addition to his practice. However, there are many of these who dislike the philosophy of the situation and believe it is a detriment to the country—this being based on the many errors of government-run enterprises already evident.

The people who are of the paternalistic, or "I deserve it" attitude, are in full accord with the program. The rest either accept it (and apathy is evident in many) or resent it. I took the opportunity of talking at length with physicians and persons in all walks of life throughout Britain and came to the conclusion that basically we are not at all unlike. The war with its exhaustion and the postwar administration made for considerable apathy. For this reason many years were lost and paternalism was fostered.

Just how the entire program was conceived is interesting. In 1911 the panel system, whereby the government began paying physicians for caring for their patients, was instituted. For many years this included only those who earned less than four hundred pounds a year. (This was equivalent to two thousand dollars but possessed a greater buying power). The program was carefully thought out and further extensions were becoming evident. The Conservative party, not the Labor party as we all have believed, was the originator of the program and was in the process of consultation (admittedly slow) with the British Medical Association, when the Labor party through its Bevan made the program a political football and with votes in mind rather than British health, thrust it through. This was greatly enhanced by the poor co-operation of the voting conservative population. The cost was estimated in 1948, when the plan was begun, at 510 million dollars. The mechanism was to be simple and it is, for the basic plan had been in effect for thirty-seven years. However, the cost in 1951 was 1.3 billion dollars and estimated at 1.5 billion dollars for 1952. The Conservative government has set a 1.2 billion dollar limit per year thereafter. However, one can see that some of the problems are being met, but slowly. Thus, as I have been told, "when we get the rough edges off and are used to the scheme, it will not be so bad."

In general then, what has happened is that a blanket scheme has hindered the progress in Britain. If the problem had been met as needed, the overwhelming cost and rather frequent misuse would not have occurred. The people now may all see personal physicians, but this is also a disadvantage for one cannot maintain his professional level and still receive adequate remuneration. He is penalized for doing a thorough job. In addition the hospitals are full and with waiting lists. As a result the nursing homes are personal costs, which fact has stimulated personal insurance coverage. The doctor may see whom he desires and treat without interference; however I have noted the bed and drug problem. The personal pride in what were voluntary supported hospitals has left and in many places an unhappy air is evident. The plan hampers the general physician and most students now plan to be specialists. As a result rural care eventually will be difficult. But certainly the crux of the entire situation stems from the disregard of the true immediate and basic needs to institute a blanket program which even a wealthy country could not have ingested at one time.

In my discussions with the dozens of physicians throughout Britain extensive interviews were possible in sixty-six instances, which is but a cross section. All agreed that expanded medical care in Britain had been necessary, but not one was pleased with the manner in which it had been handled. There was a great deal of grumbling about the British Medical Association and its desertion of their resolutions. There were many facts to substantiate their claim that from the leaders down there was a regard only for personal security, which was a sudden departure, for many wanted to be "on the ground floor." In spite of all the difficulties, medicine at the specialist level and with these general men who have outside sources of income, is nearly as good as ours. Over and above the extension of care and niceties there are several features which are worthwhile. For example, the general physician may take two weeks a year with tuition and salary for a postgraduate course. Thus all is not so bad as we are so often told.

Just how this applies to the United States is not evident immediately. As I have stated before it is impossible to compare Great Britain and the United States for the reasons indicated. What is apparent and certainly analogous is the manner in which the program went into effect. In discussing this with local physicians I have found we have been drifting into exactly the same rut of being reticent about listening to any suggestions. Rather we, through the AMA, for years have said no to all. It became evident to me that no matter how much time we spend saying no, eventually we shall be caught in a sweep, for politics has too many emotions with too few facts. British care was not at all antiquated and restricted, but it needed adjustment just as ours needs cost adjustment. What happened in place of a concrete plan by the British Medical Association you all know.

Thus, it is my feeling that a plan must be devised in medicine to preclude any possible necessity for its becoming political. I believe that a volunteer plan of the Blue Cross type is best, but that perhaps some *local* subsidization may prove necessary, as has been the case in general hospitals. Other reasons for this include the physician's too frequent misuse of the Blue Cross, the lack of an informed populace, and the to date poor public relations job done by medicine. Fortunately there is evidence of moderate but definite progress in the last two. Obviously there will be less stumping for a nationalized plan here for the next two to four years, which fact presents the ideal breathing space for positive action and the formation of a plan to bring to the public before politicians back us to our "no" wall again. The difficulty lies in the physicians' easy course of criticism with few doctors seeing beyond their own practice in the effort of establishing a necessary policy. This can be rectified by co-operation—not the type demonstrated in the British Medical Association.

Briefly I have presented the results of my experiences, observations, and studies in Great Britain. There are numerous other phases that could well warrant elaboration, such as the mishandling of the tuberculosis problem, the meager public health measures, the relative termination of the progress in industrial medicine, the varying but not promotive effect on college health, housing, et cetera. However, the conclusions which I reached through this raft of information are included Moreover, I believe there are several ways that we could combat the Truman-Ewing political enterprise and its proponents by getting on the offensive.

Let us not, for a change, "have too little too late!"

Health Service

HEMOLYTIC ANEMIA

PAUL S. HAGEN, M.D.
Minneapolis, Minnesota

HEMOLYTIC anemia is a rather common type of anemia in our hematologic experience at the Minneapolis Veterans Administration Hospital. For example, on the medical wards we are seeing at least twenty new patients a year who have hemolytic anemia. Some of these have congenital hemolytic syndromes, but in the majority the hemolytic anemia is acquired, often secondary to another disease.

Classification

Hemolytic anemia is characterized by an excessive rate of red cell destruction so that the normal 100- to 120-day life span of the red cell is shortened. In some of these patients the average life of the red cell is only a few days.

Marking of the red cells by various tracer techniques has aided greatly in the understanding of the general processes involved in the *in vivo* destruction of red cells in the various hemolytic anemias. Heavy nitrogen, radiocarbon and radioiron are useful in studying red cell dynamics. However, the most versatile method for tracing the fate of red cells utilizes the natural agglutinogens of the red cell. This method is known as the Ashby differential agglutination technique.[1] Red cells that are compatible but serologically identifiable are transfused, and the rate of their disappearance is followed. For example, Group O cells are given to a Group A recipient. Serial blood samples are drawn, the recipient's cells removed by agglutination with anti-A serum, and the donor cells which remain freely suspended are counted. These values are plotted against time on graph paper. The resulting graph shows the pattern of disappearance of the transfused cells and from this graph the average life of the transfused red cells can usually be calculated.[4] The MN blood groups are used in a similar fashion. Cross transfusion studies are useful to determine whether a hemolytic anemia is due to faulty red cells (intrinsic defect) or whether the increased rate of red cell destruction is due to environmental (extrinsic) factors. In these studies the patient's cells are transfused and followed in a normal individual while normal cells are transfused and followed in the patient. If the patient's cells disappear rapidly in the normal while normal cells live a normal length of time in the patient it is apparent that the hemolytic anemia is due to an intrinsic defect of the cell. However, if there are extrinsic hemolytic factors present in the patient, transfused normal cells will be destroyed at an increased rate. On the basis of these differential agglutination studies the hemolytic anemias fall into two major categories:[12] I. Hemolytic anemia due to intrinsically defective red cells, and II. Hemolytic anemia due to extrinsic causes. Occasionally an anemia in group I can be complicated by some extrinsic abnormality.

Hemolytic anemias due to intrinsic defects include: 1. Hereditary spherocytosis (familial hemolytic anemia, congenital hemolytic jaundice). 2. Sickle cell anemia. 3. "Mediterranean" anemia. 4. Hereditary non-spherocytic anemia. 5. Paroxysmal nocturnal hemoglobinuria. Although pernicious anemia is not a hemolytic anemia in the usual sense, the cells are abnormally constructed and have a shortened life span.[8,10,17] The hemolytic anemias due to extrinsic factors constitute a large group caused by many different agents.

Mechanisms of Abnormal Red Cell Destruction[13]

Cells with intrinsic defects are destroyed by different mechanisms depending upon the nature of the defect of the cell. For example, the sickle cell because of certain abnormalities of its hemoglobin and cytoskeleton becomes sickled when it is exposed to low oxygen tension. This abnormal shape leads to impaction of these cells in the capillaries of various organs with subsequent hemolysis. In hereditary spherocytosis the cells

Sponsored by the VA and published with the approval of the Chief Medical Director. The statements and conclusions published by the author are the result of his own study and do not necessarily reflect the opinion or policy of the Veterans Administration.

issuing from the bone marrow are thicker than normal.[2] It has been demonstrated in two different laboratories[5,22] that these thicker than normal cells are selectively trapped in the splenic pulp where they undergo changes leading to disintegration. It is believed[22] that the spherocytic cells are trapped because they cannot escape from the splenic pulp as easily as cells of normal thickness through slit-like openings into the venous sinusoids. Actually these hereditary spherocytic cells have been found to have an essentially normal life span when they are transfused into splenectomized individuals.[14] The chief reason for the success of splenectomy in this disease is now apparent. In "Mediterranean" anemias increased fragmentation of the abnormally constructed cells appears to be an important mechanism of early destruction.

The second group, hemolytic anemias due to extrinsic factors, are the hemolytic anemias more frequently encountered in our experience. In these syndromes, normal red cells are produced by the bone marrow but they are injured by a wide variety of agents which cause their early destruction. These extrinsic agents can injure the red cell envelope directly or they may interfere with the internal metabolism of the red cell leading to its disintegration. A number of these agents undoubtedly attack the cells in both general ways.

Septicemia with various bacteria, intracellular parasites, many drugs and chemicals, full thickness burns, certain animal and vegetable poisons have been noted to cause excessive red cell destruction. However, most of the acquired or "extrinsic" hemolytic anemias encountered are associated with immune body reactions. These are of several types. For example, there are isoagglutinins related to the various blood groups including Rh sensitivities. Cold hemagglutinins are another type of immune body reaction. These are often associated with some illness, such as primary atypical pneumonia, leukemia, or as we have recently seen, cirrhosis of the liver. "Cold" and "warm" hemolysins are other types of immune bodies demonstrable in hemolytic anemias.

"Extrinsic" types of hemolytic anemias are found at times with various primary diseases[19] and are often referred to as "symptomatic" hemolytic anemias.[16] "Symptomatic" hemolytic anemia is the most frequent type of hemolytic anemia we have seen. For example, we have found evidence of excessive red cell destruction as follows: rather frequently in patients who have lymphocytic leukemia, myelocytic leukemia, Hodgkin's disease and other lymphomas; in at least two patients with carcinomatosis involving the bone marrow; occasionally with cirrhosis of the liver; at times in primary atypical pneumonia when there is a high titer of cold hemagglutinins; infectious mononucleosis; "Felty's" syndrome (rheumatoid arthritis, leukopenia, anemia and splenomegaly); polyarteritis nodosa; in a patient who is a salmonella carrier and has a high antibody titer; and in a patient with "burned out" polycythemia vera who had leukemia and a huge spleen. Hemolytic anemia has been found with uremia, hyperthyroidism, lupus erythematosis, Boeck's sarcoid as well as other diseases. Among this group of hemolytic anemias due to extrinsic factors are some syndromes in which there is no apparent underlying cause for the excessive red cell destruction. These are usually referred to as "idiopathic" acquired hemolytic anemias.

In perhaps about half of these "symptomatic" and in a higher per cent of the "idiopathic" hemolytic anemias it is possible to demonstrate the presence of abnormal immune body reactions by the methods available today. However, as methods for detection of abnormal immune bodies improve it is possible that immune bodies will be demonstrable in most of these particular hemolytic anemias.

Recognition of an Increased Rate of Red Cell Destruction

The frequency of diagnosis of hemolytic processes is directly proportional to a high index of suspicion. A family history of anemia may indicate the presence of one of the congenital hemolytic anemias. The possibility of exposure to industrial chemicals such as lead, benzene, aniline and others, must be inquired into. A detailed history as to the ingestion of drugs, chemicals or animal and vegetable poisons may be revealing. This type of inquiry, for example, led to the solution of acute hemolytic anemias in certain children[23] who had eaten moth balls. The large number of diseases with which hemolytic anemias have been noted must be kept in mind. In short, whenever confronted by a patient with anemia, an excessive rate of blood destruction must be considered as one of the possible causes of the anemia.

A. *Signs indicative of increased red cell destruction.*

1. Physical findings

a. Splenomegaly.—There is a rather high degree of correlation but hemolytic anemias may be present without splenomegaly. On the other hand, splenomegaly often occurs without increased red cell destruction.

b. Jaundice.—Excessive hemolysis must always be included in the differential diagnosis of jaundice. It is important to note that excessive hemolysis is not always accompanied by jaundice. The presence or absence of jaundice depends upon the ability of the liver to excrete bilirubin.

2. Laboratory findings

a. Serum bilirubin.—If serum bilirubin increases and gives an "indirect" Van den Bergh test, increased red cell destruction is quite likely. (Characteristically, no bilirubin is found in the urine under these circumstances.) However, as indicated above, the serum bilirubin level depends upon liver function and so may or may not be elevated even though a rather marked degree of hemolysis is present.

b. Peripheral blood.—Examination of a stained blood film often leads to the diagnosis of hemolytic anemia. Spherocytosis whether due to hereditary defects of the red cells or caused by circulating injurious agents is highly suggestive of increased hemolysis. Poikilocytosis is another sign associated with a shortened life of the red cell. This may represent excessive fragmentation of the red cells which can result from chemical injury such as has been observed in naphthalene poisoning, or from abnormally formed cells as in "Mediterranean" anemia. Sickle cell anemia can occasionally be diagnosed from the ordinary stained blood film.

Signs of increased red cell regeneration in the peripheral blood may be the result of an increased rate of red cell destruction. Large cells with a bluish-gray tinge (polychromatophilic cells) are young cells and if present in increased numbers usually indicate increased red cell regeneration. The finding of nucleated red cells often has similar implications.

Basophilic stippling represents precipitation of remnants of the ribonucleoproteins which are found in early forms of the cells.[20] Heavy metal poisoning causes stippling, and increased stippling also occurs in a variety of anemias. From whatever cause, the finding of many stippled cells means an increased number of young red cells in the circulation.

c. Osmotic fragility test.—A simple two tube test[7] can be performed in the office. Because spherocytes rupture more easily than normal cells in hypotonic salt solutions, a positive test confirms the presence of spherocytes found on the blood film.

d. Reticulocyte count.—Normally only 0.5 to 1.5 per cent of the circulating red cells show reticulation. Increased numbers of reticulocytes generally indicate increased red cell regeneration. If blood loss and response to therapeutic agents can be ruled out, the increased regeneration usually results from increased red cell destruction. However, it must be emphasized that increased hemolysis may occur without a reticulocyte response.

e. Sickle cell test.—This test is indicated in every anemic patient in whom there may be even a remote chance of some Negro blood. It is best to use a chemical reducing substance such as a 2 per cent solution of sodium metabisulfite mixed in equal amounts with blood on a slide and coverslipped.[7] If the test is positive at least one important potential cause of the anemia is known.

f. Tests for abnormal immune antibodies.—Most of these should be carried out in experienced, competent laboratories. The finding of antibodies is suggestive that abnormal hemolysis is present. However, antibodies can be present without evidence of increased hemolysis, and increased hemolysis can be present without the demonstration of antibodies. The following are the usual tests for antibodies:[7,20] Coombs' test (direct and indirect), trypsinated cell test,[21] cold agglutinin titer, Donath-Landsteiner reaction, special examinations for other "cold" hemolysins, and tests for "warm" hemolysins. The acid serum test for the abnormal cells of paroxysmal nocturnal hemoglobinuria is included with this group although it is not a test for immune bodies.

One simple test for immune bodies of the cold agglutinin variety can be performed anywhere. It consists of chilling a sample of blood which has been collected into an anticoagulant. With a high titer of cold agglutinins the blood becomes granular. Upon rewarming, the blood again becomes smooth. Increased hemolysis may or may not be present when this test is positive.

g. Hemosiderinuria.—Large amounts of hemosiderin may be consistently found with chronic hemoglobinemia and hemoglobinuria, conditions which are found in paroxysmal nocturnal hemoglobinuria. This finding was recently of great help in the diagnosis of a patient with paroxysmal nocturnal hemoglobinuria.

h. Bone marrow.—Erythroid hyperplasia frequently is the result of increased demands resulting from increased hemolysis, but other causes must be strongly considered. Bone marrow examination may prove helpful by showing evidence of a primary disease such as a leukemia or carcinomatosis.

B. *Diagnostic signs of increased red cell destruction.*

1. Hemoglobinemia and hemoglobinuria

Hemoglobinemia results from intravascular hemolysis. Hemoglobinuria occurs whenever the plasma hemoglobin level exceeds the renal threshold for hemoglobin. In most of the hemolytic anemias the hemolysis takes place at a slower rate and apparently "extravascularly" because hemoglobinemia is uncommonly seen. Severe transfusion reactions and certain septicemias frequently have hemoglobinemia. Also, we have seen a patient with chronic lymphatic leukemia who had two or three acute episodes of hemoglobinemia. Paroxysmal cold and paroxysmal nocturnal hemoglobinuria regularly show hemoglobinemia. But usually the diagnosis of increased hemolysis must be made on other evidence.

2. Fecal urobilinogen

The most useful and practical means to diagnose an increased rate of red cell destruction is the quantitative determination of the average daily output of fecal urobilinogen in a four-day stool collection.[15] Although heavy nitrogen tracer studies have indicated there is more than one source of fecal urobilinogen[9] from a clinical point of view, when the fecal urobilinogen is increased an increased rate of red cell breakdown is present. For most helpfulness, the fecal urobilinogen should be related to the circulating hemoglobin mass either as an "apparent wastage"[18] figure or as a "hemolytic index" figure.[11]

It is important to realize when interpreting fecal urobilinogen values, that falsely normal values can occur. Antibiotics such as aureomycin and terramycin given even in small doses can alter the intestinal flora so that the bilirubin is not converted to urobilinogen in the usual way. Other unknown factors also interfere with this conversion. Constipation and diarrhea may lead to erroneous results. If the sample weighs less than about 300 grams, it should not be considered as an adequate four-day stool specimen.

3. Red cell tracer studies

As outlined above, the red cell tracer methods, especially the Ashby technique, not only can show the presence of increased red cell destruction but also can be used to differentiate whether intrinsic or extrinsic factors are causing the excessive breakdown. However, the isotopic tracer studies are strictly research methods, and few would agree that even the Ashby technique could be considered a clinical procedure.

In general then, the diagnosis of increased red cell destruction, in the absence of hemoglobinemia, must be made on the basis of the signs of increased red cell destruction and regeneration coupled with reliable fecal urobilinogen determinations.

Treatment of Hemolytic Anemia

Since hemolytic anemia can arise from a wide variety of causes, rational therapy demands that the pathogenesis of the excessive blood destruction must be accurately diagnosed in the individual patient. When an infectious disease is the cause, appropriate specific treatment of the infectious disease is the avenue of approach. When the hemolysis is due to toxic agents there is no specific therapy other than insurance against further exposure to the inciting agent.

Whenever severe hemolytic anemia is associated with hyperimune bodies treatment with ACTH or cortisone can be tried. There is some evidence that ACTH and cortisone reduce the titers of the antibodies. Some reports are enthusiastic about the results.[3] Our own limited experience has not been too gratifying. However, if the hemolytic process with immune antibodies is so severe as to require therapy, ACTH or cortisone should be tried if no contraindications exist.

In the patient with symptomatic hemolytic anemia, at times treatment directed at the primary disease may prove fruitful. For example, we have rarely seen patients with lymphocytic leukemia whose hemolytic processes have decreased markedly after deep x-ray therapy. In one instance the x-rays were directed to the spleen while in another patient mediastinal and axillary lymph nodes were irradiated. Blood transfusions also were given. The second patient previously had had his spleen removed.

"Idiopathic" acquired hemolytic anemia sometimes is self-limited but occasionally requires aggressive therapy: ACTH or cortisone; at times splenectomy.

Splenectomy: Splenectomy is not indicated when septicemia, parasitic invasion of the red cells, or chemical poisoning causes hemolytic anemia. However, in other hemolytic anemias, whenever the spleen is large and the hemolytic process fulminating, splenectomy may give dramatic results. Often, however, there is no real response. In certain patients with leukemia, when excessive hemolysis is the immediate problem, splenectomy may prove beneficial in reducing the transfusion demands.[6] Splenectomy can be expected to give good results nearly 100 per cent of the time only in hereditary spherocytosis; otherwise the results are variable. Splenectomy itself has a low mortality rate, but partly because of the danger of postoperative thrombotic processes, we have been rather conservative in recommending the procedure.

Blood transfusions: For supportive therapy blood transfusions are the mainstay. However, there is greater danger of transfusion reactions in patients with hemolytic anemia than in others. This is especially true in those who have hyperimmune bodies. With chronic hemolysis requiring repeated transfusions the danger of producing exogenous hemosiderosis is real. Therefore, to help limit the amount of blood transfused, it is best not to attempt to keep the hemoglobin higher than 10 gm. per 100 ml. of blood.

Iron: In general, iron should not be given to patients with hemolytic anemia. They are not losing iron and therefore do not need iron. Theoretically, iron therapy is objectionable because it adds to the iron stores of the body. The iron stores are increased by the iron of transfused blood cells and so iron therapy may help to produce exogenous hemosiderosis. Paroxysmal nocturnal hemoglobinuria with its consistent loss of iron (hemosiderinuria) is an exception.

Liver (Vitamin B_{12}): Of no use in the hemolytic anemias.

Veterans Administration Hospital

DANGER OF AMMONIUM CHLORIDE ACIDOSIS

Report of Case

JAMES MYHRE, M.D.
Minneapolis, Minnesota

ENTERIC-COATED ammonium chloride is a valuable diuretic agent in the treatment of congestive heart failure. When it is used in conjunction with the mercurial diuretics, it enhances diuresis by potentiating the action of the organic mercurial. These valuable drugs are in common general usage. It is felt that the danger of acidosis from ammonium chloride often is not too well appreciated and therefore an illustrative case is being reported to call attention to this real danger.

The diuretic action of ammonium chloride may be due to two factors.[1] One hypothesis is that when the kidney is presented with an excess of chloride ions, it excretes the chloride with water. Another is that the increased body acidity from the "acid producing" salt causes the increased excretion of salt with water to maintain a balanced composition of body fluids. The exact method of potentiation of the diuretic action of the organic mecurial diuretics by ammonium chloride is as yet not completely defined.[2]

Case 1.—A seventy-five-year-old white woman was first seen on June 12, 1951, complaining of shortness of breath on exertion, need of being propped up on four or five pillows to sleep, and swelling of the ankles for two years. She also complained of a severe lower lumbar backache since gaining a great but inexact amount of weight during the past six months. She had been living alone, had been quite depressed and had been eating poorly. There was a history of high blood pressure of twenty years duration.

On physical examination she was 5 feet 1½ inches tall and weighed 231 pounds. There was bilateral thickening of the ear drums, purulent crusting in the right nasal cavity and cloudiness of both maxillary sinuses on transillumination. There was marked fetor oris and a mild generalized pyorrhea alveolaris. Good visualization of the fundi was not possible. The blood pressure in the right and left arms was 180/120 mm. Hg. The heart was enlarged to the left and the sounds were distant. Moist râles were heard at both lung bases. A sharp liver edge was found four fingers below the right costal margin. The spine was rather fixed with only forward and backward bending and pain on bending to either side, especially to the right. There was moderate pitting edema of the lower extremities. Both ankle jerks were absent.

Laboratory Studies.—There were 14.3 grams % (Evelyn) or 91.7 per cent hemoglobin with 4.88 million red blood cells and a hematocrit of 45 per cent. There were 10,800 white blood cells with a normal differential count. The sedimentation rate was 62 millimeters per hour (Westergren). The urine had a specific gravity of 1.020 with a trace of albumin and eight to ten white blood cells in a high-powered field. The Kolmer-Wassermann was four plus. Two stool specimens were negative for occult blood. An agglutination test for brucellosis was negative. The vital capacity was 1.2 litres of 39 per cent. The calcium gluconate circulation time was twenty-one seconds (normal ten to sixteen seconds). An electrocardiogram indicated myocardial damage with a low T_1, low T waves in the V leads, and a left axis deviation. X-ray examination of the lumbosacral spine showed hypertrophic arthritis and osteoporosis of the lumbar spine and minimal hypertrophic arthritis of both sacroiliac joints.

Clinical Course.—The patient was admitted to the hospital on June 21, 1951, weighing 228 pounds, and was placed on an 800 calorie salt-free diet (1 gm. of sodium per day), digitalis, ammonium chloride, and mercurial diuretics. The blood urea nitrogen on admission was 7.8 mg. per cent. She was given 1 cc. mercuhydrin on the first hospital day, 1.5 cc. on the fifth hospital day, and 2 cc. on the ninth hospital day. She was given 2 gm. of enteric-coated ammonium chloride four times daily for the first twelve days. On approximately the tenth hospital day she became quite anorexic, and this was followed by severe weakness, clouding of her sensorium, confusion, and incontinence of urine. The CO_2 combining power on the twelfth hospital day was 26 volumes per cent with a plasma chloride of 674 mg. per cent (normal 540-620) and a blood urea nitrogen of 62.5 mg. per cent. The blood sugar was 119 mg. per cent, and the serum sodium was 149 milli-equivalents (normal 138-146). The serum potassium was 16 mg. per cent (normal 16-22). Four times in twenty-four hours she was slowly given 250 cc. of five per cent sodium bicarbonate intravenously. Definite clinical improvement was observed in twelve hours, and in three days the CO_2 combining power was 56 volumes per cent with a plasma chloride of 639 mg. per cent. On the eighteenth hospital day the blood urea nitrogen was normal with a plasma chloride of 558. From then on she tolerated the salt-free diet and digitoxin well and was discharged on July 17, 1951 (twenty-sixth hospital day) weighing 213 pounds. In May 1952, the patient was feeling well and the urinalysis was normal with a maximum specific gravity of 1.024 on a urine concentration test.

Conclusions

A patient with congestive heart failure became anorexic, weak, confused, incontinent, and semicomatose during treatment including ammonium chloride. A cerebrovascular accident and salt depletion syndrome had to be considered. The symptoms were, however, proved to be caused by ammonium chloride acidosis, and the patient responded dramatically to intravenously administered sodium bicarbonate. This entity can be rather subtle especially when limited laboratory facilities are available. Ammonium chloride must be used cautiously where associated renal disease is suspected or present, and this is difficult to establish in congestive heart failure. Renal insufficiency in congestive heart failure would only be suspected in the presence of albuminuria, oliguria, and mild elevation of the blood urea nitrogen or non-protein nitrogen. Significant renal disease should, however, be greatly suspected[3] when there is marked persistent albuminuria, low-fixed specific gravity, and elevation of the blood non-protein nitrogen above 60 mg. per cent. In these instances ammonium chloride must be administered with extreme caution. It is believed that ammonium chloride for diuretic purposes should not be given over three days a week unless repeated CO_2 combining power determinations are made.

THE SOCIALIST-COMMUNIST IDEA

As a teacher in public schools, I find that the socialist-communist idea of taking "from each according to his ability" and giving "to each according to his need" is now generally accepted without question by most of our pupils. In an effort to explain the fallacy in this theory, I sometimes try this approach with my pupils:

When one of the brighter or harder-working pupils makes a grade of 95 on a test, I suggest that I take away 20 points and give them to a student who has made only 55 points on his test. Thus each would contribute according to his ability and—since both would have a passing mark—each would receive according to his need. After I have juggled the grades of all the other pupils in this fashion, the result is usually a "common ownership" grade of between 75 and 80—the minimum needed for passing, or for survival. Then I speculate with the pupils as to the probable results if I actually used the socialistic theory for grading papers.

First, the highly productive pupils—and they are always a minority in school as well as in life—would soon lose all incentive for producing. Why strive to make a high grade if part of it is taken from you by "authority" and given to someone else?

Second, the less productive pupils—a majority in school or elsewhere—would, for a time, be relieved of the necessity to study or to produce. This socialist-communist system would continue until the high producers had sunk—or had been driven down—to the level of the low producers. At that point, in order for anyone to survive, the "authority" would have no alternative but to begin a system of compulsory labor and punishments against even the low producers. They, of course, would then complain bitterly, but without understanding.

Finally, I return the discussion to the ideas of freedom and enterprise—the market economy—where each person has freedom of choice, and is responsible for his own decisions and welfare.

Gratifyingly enough, most of my pupils then understand what I mean when I explain that socialism—even in democracy—will eventually result in a living death for all except the "authorities" and a few of their favorite lackeys.—A letter from THOMAS J. SHELLY, teacher of economics and history, Yonkers High School, Linden and Poplar Streets, Yonkers 2, N. Y., Jan. 20, 1951. *Pennsylvania Medical Journal*, December, 1952.

FRIEDLANDER'S PNEUMONIA

JOHN P. DAHLSTET, M.D.
Mankato, Minnesota

A CORRECT diagnosis is facilitated by the physician's bearing in mind the existent possibilities and probabilities. There is perhaps a tendency in recent years to ascribe many obscure infections to a "virus" without having first exhausted the other existent possibilities. It seems, therefore, apropos to call attention at this time to Friedlander pneumonia.

While Friedlander's pneumonia is a relatively infrequent type—having been estimated at from 0.5 to 5.0 per cent of all pneumonias—it is nonethe-less important. It is a severe disease with a high mortality—of 70 to 80 per cent—and with a high incidence of complications in those cases which survive.

Since the ordinary types of pneumonia have shown a relative decline, and the atypical pneumonias a relative increase in incidence, and because Friedlander's responds not to penicillin, Aureomycin or Terramycin, early recognition and the institution of proper therapy are of paramount importance. The causative agent is the Friedlander bacillus, or *Bacillus mucosus capsulatus,* a short Gram-negative non motile rod with a thick capsule. Friedlander's pneumonia is more common in males in a ratio of five to one. It is most common in the age bracket of forty to sixty-five, only a few cases having been reported in children. There is a higher incidence in the winter months. Alcoholism, malnutrition and other debilitating influences are thought to be important predisposing factors. Any lobe or combination of lobes may be affected. The consolidation is often lobular or confluent rather than lobar. The involved portion of the lung is voluminous. There is considerable plural inflammation with a reddish, fibrinous exudate. The alveolar exudate is abundant, and characteristically tenacious. The lung parenchyma is frequently destroyed with frequent formation of pus-filled abscesses. Pulmonary edema, pleural effusion, empyema, and pericarditis are complications often found at autopsy, and jaundice occurs in over 10 per cent of acute cases. The disease usually begins abruptly with the onset of a more or less productive cough, pleuritis, perhaps hemoptysis, and chills. There may be cyanosis and dyspnea.

The patient may appear desperately ill, much more so than the physical findings would indicate, for the physical signs of this disease are not diagnostic. The temperature most commonly is 102 degrees or under, and there may be only a relatively slight leukocytosis. The sputum is thick and tenacious, at times very viscid. Until the use of streptomycin altered the outcome, the usual course was to an early death in two to six days, with a mortality rate of from 70 to 80 per cent. A few patients respond quickly and completely, while a third group progresses to a chronic form of this disease, with the formation of one or more thin walled abscesses. It is felt there is a definite tendency for tuberculosis to develop subsequent to Friedlander's pneumonia.

This disease must be differentiated from other bacterial pneumonias—influenzal, pneumococcic, streptococci, and staphylococcic, and from the so-called virus pneumonias. The patient with Friedlander's infection is usually a male over forty years of age, often with a history of a preceding chronic respiratory infection. He is obviously gravely ill. Herpes labialis—as seen frequently in lobar pneumonia—is uncommon; the sputum is usually thick, glairy, mucoid, and often red. Physical findings are not commensurate with the degree of lung involvement. In pneumococcic pneumonia the temperature is usually high and the physical findings of lobar consolidation characteristic. The respirations are short, grunting, and rapid, and the sputum rust colored. A well marked leukocytosis is noted, predominantly of the polymorphonuclear type. In hemolytic streptococcic pneumonia, the disease often follows infection elsewhere in the body with pharyngitis, laryngitis, and tracheobronchitis commonly preceding pneumonia. Staphylococcic pneumonia is usually seen in early childhood, as is the influenzal pneumonia. Virus pneumonia is more common in young adults and its onset tends to be gradual, rarely accompanied by a true chill. Weakness and persistent cough

---

Read at the Annual Meeting of the Southern Minnesota Medical Association, Austin, Minnesota, September 8, 1952.

are common, but severe prostration and death are rare.

On x-ray, Friedlander's pneumonia must be differentiated from pulmonary tuberculosis and neoplasm, and from an x-ray standpoint three different classifications of Friedlander's have been noted. First of these is the massive lobar consolidation type in which a single lobe or an entire lung field may be obscured by a dense uniform exudate which may give the appearance of bulging. Second of these is the lobular consolidation type with a patchy irregular density later becoming confluent. The third group is a chronic form characterized by lung abscess formation and pulmonary suppuration. The abscesses may form relatively early in the course of Friedlander's infection and apparently are due to parenchymal destruction with filling of the area by a thick, tenacious exudate accompanied by atelectasis and ischemia. Changes may closely resemble tuberculosis or bronchiectasis.

Case Report

The patient is a fifty-nine-year-old white male mechanic. His father died of pulmonary tuberculosis. The patient had been well until the latter part of April, 1952, although he stated he had lost some 25 to 30 pounds in weight since January, 1952. His initial symptoms had been pain in the right scapular region with generalized malaise, and a persistent and unproductive cough.

During the first week of May, 1952, he noted not only an increasing weakness, but the onset of chills and fever, and some productiveness of the cough. He came to my office on May 9, scarcely able to drag himself into the reception room. Examination at that time revealed a temperature of 100.8°F, respiration of 28. and a pulse rate of 84. The eyes, ears, nose, and throat, were not remarkable. There was no cervical or other adenopathy, and the skin was moist with no cyanosis or flushing. The heart was regular at a rate of eighty-four with the tones distant and the left heart border 13 cm. to the left of the midsternal line. The blood pressure was 100/60 mm. Hg. A few moist rales were heard at each base posteriorly and there was thought to be diminished resonance in the right interscapular area with a slight decrease in breath sounds over the same region. The abdomen was soft, flat, nontender, with liver, kidneys, and spleen not palpable. The genito-urinary system was normal, and a rectal examination negative. The extremities were not remarkable. In December of 1951, this man had had a thorough examination including a chest x-ray which was essentially negative.

The patient was hospitalized on May 9, and a chest film made in addition to a complete blood count, sedimentation rate, and urinalysis. The hemoglobin at that time was 11.6 gm., the red count was 4 million, the white blood count 5,200, and the sedimentation rate by the Westergren method was 115 mm. per hour. The chest film revealed a marked, fairly soft infiltration throughout most of the right lung field, most marked in the upper portion with fibroid strands radiating upward and laterally from the right hilum.

Because the patient appeared so desperately ill, intensive therapy with penicillin and Aureomycin was begun at once. He was also digitalized because the moist rales at each base and the increase in heart size on x-ray would indicate a beginning decompensation. Sputum was obtained for bacteriological study and for Papanicolaou stain, but because of somewhat limited laboratory facilities locally, the specimen was sent to a metropolitan laboratory. Penicillin and Aureomycin were continued, and because the patient appeared clinically to have an overwhelming infection, it was decided to support him further with whole blood transfusions, which were given on May 13 and May 14. A 1:1000, and subsequently a 1:100 Mantoux test were both negative. Reports from the State Board of Health repeatedly were negative for acid-fast bacilli. However, for some reason or another we were unable to receive a report of any other pathogenic flora. On May 19, dihydrostreptomycin 0.5 Gram every twelve hours, and triple sulfa 1 gm. four times daily was substituted for penicillin and Aureomycin. Subsequent to this the patient's temperature remained below 100°F orally, and he improved generally with only little productive cough. However, the chest films did not reveal a commensurate improvement. On May 19, a heavier degree of infiltration was noted in the right upper lung field with evidence of multiple cystic areas as had been seen before. On May 26, a slight band of infiltration had begun in the second and third innerspace on the left with no change on the right. On June 2, this infiltration on the left had increased. Meanwhile, on May 30, the patient had refused further injections and finally on June 5 left the hospital to remain in bed at home. On June 3, however, before his dismissal from the hospital, a bronchoscopy was performed by Dr. J. D. Sjoding. This was essentially negative, but some exudate was aspirated and bacteriological studies on the exudate confirmed the diagnosis of Friedlander's pneumonia, and the patient was then prevailed upon to continue streptomycin, and triple sulfa. In three days more he became afebrile and gained in strength and appetite. After four days with no fever the medications were stopped. He continued to improve until on July 18 when he was suddenly stricken with a severe chill and his temperature rose to 103°F. Dihydrostreptomycin in 0.5 Gram doses twice daily was reinstituted, and the triple sulfa in one gram doses four times daily was also begun. He responded nicely, clinically, and has continued to do so until the present time, although there is still considerable infiltration in the left upper lung field on x-ray.

The patient has now agreed to continue medication as long as I consider it necessary, and at the present time remains afebrile, and feels well generally. It is to be hoped that he will continue to improve, and that he may progress to a favorable outcome without the necessity for surgical interference.

(Continued on Page 144)

THE RESPONSIBILITY OF THE PRACTICING PHYSICIAN AND HEALTH DEPARTMENT IN THE CARE OF THE AGED

ROBERT N. BARR, M.D.
Minneapolis, Minnesota

MINNESOTA has been fortunate not only in its natural resources but in the people that first settled in this area even when it was known as a part of the Dakota Territory. They were persons of high ideals, who believed in local independence of government, universal education, and individual initiative and responsibility. They put these convictions into action as is illustrated by our township form of government, the provision for a University in our State Constitution and the constitutional provision that two sections of land in every township in the State be set aside for school purposes.

These convictions have persisted and today color our present thinking and action and have had a definite effect on our present form of health organization and activities. We believe they account for the fact that Minnesota was the third state to organize a State Department of Health in 1872 through the leadership of Dr. Charles N. Hewitt and the State Medical Association; for the fact that the Board of Health consisting of nine members trained in sanitary science and appointed by the governor serving overlapping terms of three years has never been dominated by partisan politics, and that during this entire period, 1872 to date, we have had only four state health officers. Our state's health officer and its health staff have enjoyed the prestige of being leaders in the many health fields at both the state and national level.

We believe that these early activities and principles of organization, administration and health programs account for the fact that there has always been a close working relationship among the medical, nursing and dental professions, the hospitals, the University of Minnesota, the many voluntary agencies interested in health problems, and the State Department of Health. Likewise similar relations have been established with the numerous other official and non-official agencies whose program and services parallel or even in some instances, overlap those of the Department of Health. For example, in the early years, the Health Department laboratories and most of its services were moved to the University campus; thus the University of Minnesota Medical School and the State Board of Health jointly employed certain technical personnel in order to be able to secure men of outstanding ability and national reputation. This is no longer necessary and has been discontinued, but this relationship is still a real incentive in attracting staff for both organizations, and each organization gives the other certain technical advice and assistance. The Department of Health provides laboratory service to the University Hospitals and Health Service and instruction in certain public health and laboratory courses. Most of the health officers of the townships, villages, cities and counties in Minnesota are local practicing physicians under the general supervision of the State Board of Health who "cause all laws and regulations relating to the public health to be obeyed and enforced."

In 1911, the medical profession, the Minnesota Public Health Association (Tuberculosis Association) and the Minnesota Department of Health completed a study relative to the state's need for sanatoria and an accelerated tuberculosis control program. In 1913 the Legislature provided for the organization of county and multicounty sanatorium commissions, appropriated funds to aid in the construction and equipment of sanatoria and funds to subsidize the treatment of the patients. By 1920, Minnesota had fourteen county sanatoria in addition to its state sanatorium. The bed totals of these institutions greatly exceeded the present accepted standard of 2.5 beds for each annual death from tuberculosis.

Today several of these local sanatoria, having served their purpose, are being converted to meet the need for nursing homes and old people's homes. For many years the care and medical treatment of patients in sanatoria have been reviewed regularly by a committee of physicians outstanding in the field of tuberculosis. This committee is nominated by the Minnesota Trudeau Society and officially appointed by the State Board of Health.

Dr. Barr is with the Minnesota Department of Health.
Read at the Annual Meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 8, 1952.

TABLE I. DEATHS IN MINNESOTA BY OCCURRENCE, 1951

Cause of Death	Total	Per Cent
Total	28,145	100
Communicable Disease	1,216	4.3
Accidental Deaths	1,805	6.5
Infant Deaths	1,918	6.9
Chronic Degenerative Diseases	20,153	71.6
Other	3,053	10.8

TABLE II. SHIFT IN AGE GROUPS

	1900	1940	1950
Number Persons 65 Years and Over in Minnesota	66,771	212,618	259,309
Percentage of Total Population	3.8%	7.6%	8.7%

The increase of twenty years in our life expectancy since 1900 is due largely to the reduction in infant deaths and deaths due to communicable diseases. A review of Minnesota's 1951 vital statistics records revealed that Minnesota had the greatest number of live births in its history, 80,047, a rate of 26.5 per 1,000 of population and that only twenty-seven mothers lost their lives as a result of childbirth (a maternal death rate of .3 per 1,000 live births, the lowest rate in Minnesota's history).

Communicable diseases as a cause of death and disability are rapidly becoming relatively unimportant and, concurrently, the so-called chronic or degenerative diseases commonly associated with older age are of prime importance (Table I).

Table I shows a new low in communicable disease deaths (1,216). It is noteworthy that 84.3 per cent (1,025) of these deaths were due to pneumonia and influenza (706), tuberculosis (256) and syphilis (63), of which 75 per cent (765) occurred at age forty-five and over and 49 per cent (498) occurred at age sixty-five and over. Thus these communicable diseases have, for all practical purposes, become diseases of middle and older age. The remaining 191 deaths were due to all other communicable diseases combined and represent only .6 per cent of all deaths. It is of interest that in 1951, Minnesota's population exceeded 3,000,000 (estimate 3,018,163).

On the other hand, accidents as a cause of death and disability show only a moderate decline over the years. They are today the leading cause of death between the ages of one and thirty-five and are responsible for almost 40 per cent of deaths in children (ages one to nineteen).

TABLE III. HOSPITAL BEDS

Category	Total Beds Needed	Existing Acceptable Beds*	Per Cent of Needs Met
General	13,715	10,695	78
Mental	14,912	9,542	64
Chronic	5,963	409	7
Tuberculosis	1,040	1,855	100
Total	35,630	22,501	63%

*Beds housed in fire-resistive quarters.

With more than 70 per cent of our deaths being due to chronic disease it appears that the answer to the problem for all of us was supplied years ago by Dr. William Osler who stated: "The way to enjoy a long and healthy life is to get yourself a chronic disease and then take care of the disease."

The progressive aging of our population is one of the factors responsible for the growing importance of the problem of chronic disease. Table II demonstrates the shift in the number of persons in the older age group in Minnesota during the last fifty years.

It is estimated that this proportion may again be doubled in another twenty-five years. Some of the problems we are faced with today with respect to the care of this group of the population include health and medical care, rehabilitation, employment, housing and living arrangements, recreation, education and welfare. A complete change in the concept of living must be developed for the person of older age if all of us are to maintain our present standard of living. The state has set up a Commission on Aging which is developing information which may aid in providing some of the answers to this problem.

The Hospital Survey and Construction (Hill-Burton) Program is aiding appreciably toward providing good hospital facilities for the state. With the $11,897,218 made available during the first six years, 1,904 additional hospital beds, 180 beds in two nurses' homes and two public health centers have been provided in thirty-eight projects which are completed or in various stages of construction.

The figures in Table III are presented to show the need for additional hospital facilities in Minnesota. (Data based on 1952 State Plan Revision)

There are sixty-six general hospitals which are completely or partially non-fire-resistive containing 1,997 beds which are in need of replacement. These present a serious hazard to life and every effort is being made, in co-operation with the office of the State Fire Marshal to encourage these replacements or the installation of sprinkler systems as rapidly as possible.

Many institutions, although fire-resistive in character, have much to be desired from the standpoint of good services, adequate space, and desirable functional arrangement to insure economy of operation. With the assistance of hospital, medical, nursing, architectural and related groups, regulations for hospitals are now being developed which will raise standards, thereby insuring safe and high quality care for all persons admitted.

There are 288 institutions (nursing homes, boarding care homes and homes for the aged) providing care for this older age group. Many of these are crowded and have long waiting lists. Of the total 9,088 beds, only 2,886 are housed in fire-resistive quarters. Many of these homes lack good facilities and equipment for care; personnel, particularly registered and licensed practical nurses, are in short supply for staffing. In communities where new hospitals are built, the old hospital is frequently converted to a nursing home or a home for the aged. With the addition of a sprinkler system such a facility would aid as a temporary expedient in relieving this ever-growing problem. However, all communities must realize their responsibilities for providing the modern physical facilities which will be well operated and well staffed to assure that all older people who cannot remain in their own homes are kept as healthy and independent as possible. Community groups are also responsible for fulfilling the social, religious, educational and recreational needs of these individuals. New regulations for the construction, equipment, maintenance, operation, and licensing of nursing homes and boarding care homes became effective in February, 1952. Requirements for medical attendance, nursing and other personnel, patient areas, as well as furnishings and equipment for care are outlined and attempts are now being made to classify the existing homes in the state. Educational programs to assist institutions to meet standards, institutes for nursing home operators and superintendents of homes for the aged as well as surveys of existing facilities and needs have been undertaken.

A broad educational program must be developed to teach people the value of good medical services and good hospital and related care facilities and how they can live longer, happier lives by making use of them. Periodic physical examinations are especially indicated during middle life and continuing throughout the declining years. In this way, the incidence and severity of chronic illness can be reduced and the time postponed when greater use of these facilities becomes necessary. As a comparable example, a great deal has been accomplished in the field of maternal and child health by providing good, basic obstetrical training in our medical schools, by encouraging patients to seek the services of their physicians early during the course of pregnancy and by providing good hospital facilities in the community. Most of the deliveries (98.6 per cent) are now occurring in hospitals and practically all of the births are attended by qualified physicians. This is the reason for Minnesota's low rates in maternal and infant mortality. Many of us believe that such services have set a pattern or guide that should be carefully analyzed and followed in attacking the present-day problem of the chronic diseases. Also important is the development and expansion of diagnostic services and the recruitment and training of a sufficient number of personnel to provide preventive service, early recognition of the disabling diseases and adequate rehabilitation. This includes physicians trained in physical medicine and rehabilitation, orthopedics and related fields as well as the necessary therapists. A more adequate supply of pathologists, radiologists, and laboratory and x-ray technicians must also be provided.

With adequate rehabilitation facilities and expert personnel, much can be done for patients doomed to invalidism and dependent upon the community for support. Even a partial remedy would contribute materially in easing some of the tax load carried by the earning public. Minnesota lacks well-equipped facilities and qualified personnel to provide such services in that it has only 7 per cent of its needs met in the chronic disease hospital category.

Without question there is probably not a single physician in Minnesota who has not recognized some of these problems relative to his own community and who was not, in many instances, made real attempts to resolve some of them. The profession as a group under the guidance of the Minnesota Medical Association has, in the past, played the leading roll in the solution of the problems of communicable diseases and maternal and child health. As a result of their accomplishments they have, so to speak, actually created the problem of the care of the aged by extending the lives of the people of Minnesota to the point where, during the past year, the average age of death was sixty-three years. Today society again looks to the medical profession for leadership in resolving the ever-growing problem of protection of the health and care of the aged.

Official agencies such as the State Health Department, the Welfare Department, the Department of Institutions as well as local government and voluntary agencies can assist greatly in providing facilities, the training of personnel to operate such facilities and the education of the public in making use of facilities and services in the local community in the same way as was done in reducing maternal and infant deaths in Minnesota. In this program, government assumed in almost every instance the role which most of us believe to be its proper place.

1. It assisted in providing hospital facilities.
2. It assisted in providing training facilities and services for medical, hospital and other auxiliary personnel.
3. It provided certain laboratory services that could be most efficiently and economically performed at the State level (as, for example, the bacteriological and serological services of the State Department of Health).
4. Through its health services it assisted community educational services and programs to encourage the proper use of medical facilities and services at the community level.
5. Through its welfare department in co-operation with the medical profession it provided means for paying for medical and hospital services for the medically indigent.
6. It recorded the births and deaths.

In the last analysis, government in the maternal and child health program assisted essentially only at those levels where the individual and the local community had need and could not economically and efficiently make provision for such. It would thus appear that in the maternal and child health program, we have developed a procedure that should be used as a guide in the solution of the problem of our aging population and its associated chronic degenerative diseases.

The Minnesota Medical Association is still looking ahead in the maternal and child health field by conducting a continuous maternal mortality study in Minnesota. It has taken the leadership in developing a pilot study of the neonatal deaths in Hennepin County. It instigated a study of the needs for trained laboratory personnel in doctors' offices and hospital laboratories that will result in better training of present laboratory technologists and laboratory aides. This will also increase the number of such trained persons that will be available in the future. It assisted the Minnesota Hospital Association in developing legislative provisions to improve the facilities and services of Minnesota hospitals and related institutions.

The results of these and many other similar undertakings have been so outstanding that they are being followed in many other states. For example, eleven states this year have requested information in detail about the maternal mortality study.

Minnesota's first statewide maternal mortality study was conducted in 1941-1942 (July 1, 1941-June 30, 1942). It was resumed in 1950 and is now in its third consecutive year. It is a joint undertaking of the Minnesota Medical Association and the Minnesota Department of Health which receives the co-operation of the Minnesota Hospital Association and the Department of Obstetrics of the University of Minnesota. Yet it must be emphasized that this is primarily a study carried out by the Minnesota Medical Association in an effort to reduce preventable deaths by eliminating all possible hazards of pregnancy and childbirth.

In 1941, Minnesota vital statistics records reported 54,542 live births, of which 73 per cent occurred in hospitals, 107 maternal deaths (a rate of 2 per 1,000 live births) of which 73 per cent were considered preventable by the study committee. In 1951, we had 80,047 live births of which 98.6 per cent occurred in hospitals. There were twenty-seven maternal deaths (a rate of .3 per 1,000 live births) and only 30 per cent were considered to be preventable by the study committee. The major causes of maternal deaths are still toxemia, hemorrhage, infection, heart disease and anesthetics.

These study reports are invaluable in their use for the education and guidance of physicians and hospital staffs as well as for under-graduate training.

Perhaps their value is still greater in the public recognition that busy members of the medical profession are giving freely of their time in making such a study and in informing all members of the profession as to the results and that these same individuals are assisting the Minnesota Department of Health and Minnesota's hospitals in developing hospital facilities, services and standards in order to prevent further deaths.

A consideration of the pertinent health problems of the people of Minnesota would seem to indicate that those responsible for the administration of health services might well re-evaluate their entire program and place emphasis on those problems which are of greatest importance and where the tax dollar expended can accomplish the greatest good for the majority of the people. Certainly, the care of the chronically ill and the aged with their associated disabilities and the provision of rehabilitation services should receive first consideration.

Emphasis which was previously placed on communicable disease control, maternal and child health, environmental sanitation, et cetera, by those administering public health services should be redirected to these more pressing problems without losing sight of the fact that certain basic control measures must be maintained. For example, in the field of public health nursing this may well mean emphasis on home nursing care and the teaching of people and home makers in the care of the aged and infirm. It undoubtedly also means an expansion of these services to include the provision of advice and assistance particularly to the small nursing homes, homes for the aged and boarding care homes. In like manner, there may be considerable shifting of the emphasis of the services of other public health professions such as public health engineering, health education, nutrition, et cetera. Such re-evaluation will undoubtedly have an impact on the basic factors which determine the size, location, areas served and staffing needs of local health departments and may result in radical changes in the present thinking relative to the basic functions of local health services.

In conclusion, the solution of our present health problems would appear to be based on the provision of good facilities in the community including general hospitals, chronic disease units of general hospitals, rehabilitation centers, nursing homes, homes for the aged and boarding care homes. The second need is that of an adequate supply of well-trained medical and related personnel to provide the preventive and treatment services for the aged and to staff these institutions. This includes not only physicians trained in physical medicine and rehabilitation, geriatrics and related fields, but also well-trained physiotherapists, occupational therapists, laboratory personnel and other allied medical groups. A third need is the development of the recognition on the part of the people as to the importance and magnitude of the problem and the need for each individual to recognize that he has a responsibility to protect himself and his family by first assisting in providing for and then making use of the facilities and services available in his community. Only by so doing can we expect to prevent, cure or at least alleviate chronic illness and its associated disabilities.

The people of Minnesota are interested and searching for guidance in the problems of the aged. We are sure that individually and collectively the medical profession will continue to supply such guidance.

MEDICAL CARE REGARDLESS OF ABILITY TO PAY

Attention is called to a house action which strongly supported programs offering to provide the services of a physician to anyone unable to pay for them.

The House supported the Board of Trustees plea that the AMA "heartily endorse such medical care programs."

The reference committee report, as adopted by the House, follows:

"Protests have been made at various times that medical care is being denied certain individuals because of its cost. As is well known, the prime object of the medical profession is to serve humanity, regardless of reward or financial gain, and with a view to implementation of this principle a number of county medical societies have successfully conducted and publicized programs offering to provide the services of a physician to anyone unable to pay for them, which we believe have conclusively answered such protests.

"The Board of Trustees urges that the American Medical Association heartily endorse such medical care programs and undertake an energetic campaign to implement them, that the constituent state medical societies be encouraged to organize and vigorously promote similar campaigns embodying the principles of such programs, and that these campaigns be made known to the public through every effective medium of communication."—AMA Secretary's Letter, Jan. 12, 1953.

THE USE OF HYDROCORTISONE ACETATE (COMPOUND F ACETATE) IN THE TREATMENT OF POSTTRAUMATIC BURSITIS OF THE KNEE AND ELBOW

EDWARD D. HENDERSON, M.D. and CHARLES C. HENDERSON, M.D.
Rochester, Minnesota

Within recent months hydrocortisone acetate, or compound F acetate (hereinafter referred to as "compound F") has been made available clinically for use as a local antiarthritic agent, and its effect in rheumatoid arthritis has been recognized. However, the beneficial effect appears to be somewhat nonspecific. This fact was observed in isolated patients in whom posttraumatic effusion in knee joints, particularly in those affected with osteoarthritis, was promptly reduced by the intra-articular injection of compound F. Hollander and co-workers[1] tell of their experience in the use of compound F in arthritic joints. Their series includes thirteen patients with various types of bursitis, ten of whom had acute bursitis or tendinitis of the shoulder. Three other patients treated, two with olecranon bursitis and one with prepatellar bursitis, showed marked improvement continuing for a time.

The Present Study

We wish to report on a group of patients with posttraumatic bursitis of the knee and elbow who were treated with compound F at the Mayo Clinic during the past four months. The report is confined to these cases because they present the best opportunity for the objective and direct observation of the results of treatment as well as the judging of subjective improvement. In addition, in these patients the technique of treatment was easily carried out because of the accessibility of the involved bursae. Data on fifteen patients are presented. Four are those of olecranon bursitis, ten are those of prepatellar bursitis, and one is that of pretibial bursitis. The pertinent data on these patients are presented in Table I. Cases 4 and 6 are reported in some detail.

Case 4.—A white woman, fifty-four years old, employed as a maid in a local hotel, came to the Mayo Clinic complaining of pain, tenderness and swelling over the right kneecap of ten days' duration. She had no other complaints and the results of a recent general physical examination had been within normal limits. The patient was found to have a mildly tender, fluctuant mass anterior to the right patella (Fig. 1.) A diagnosis of prepatellar bursitis or "housemaid's knee" was made. The skin over the bursa was cleaned with soap and water, an antiseptic applied and a wheal made with 1 per cent solution of procaine hydrochloride. A 20-gauge needle was then inserted into the bursa and about 8 cc. of dark, bloody-appearing fluid aspirated into a large syringe. The needle was left in place and the aspirating syringe changed for a small syringe containing 12.5 mg. of compound F in a volume of 0.5 cc. The hormone was injected, the needle withdrawn and a dressing applied. The patient was allowed to return to work, but was asked to stay off her knees for at least a week. When she returned a week later, she stated that she had noticed complete relief from pain, tenderness and swelling in the knee within twenty-four hours after the injection. She returned to work as a hotel maid, being on her knees for several hours each day and remained symptom-free for six weeks. At the end of this time the prepatellar bursa gradually began to refill with fluid. The same procedure was then repeated, again with good results as of the date of this report.

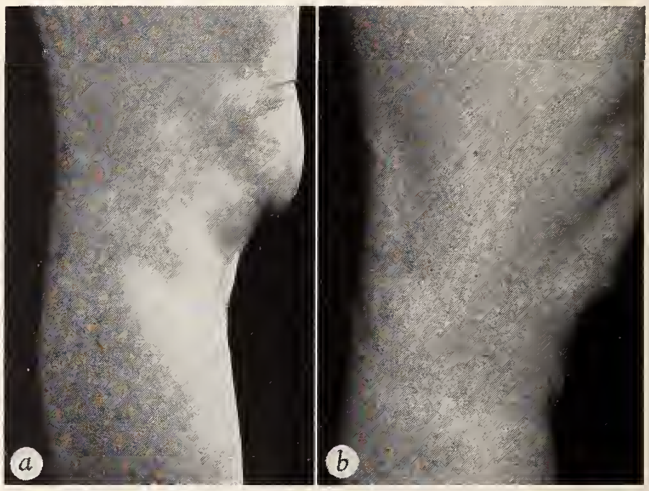

Fig. 1*a* and *b*. Prepatellar bursitis of the right knee before and seven days after injection of compound F.

Case 6.—A patient came in complaining of a painful swelling over the tip of the right elbow of four weeks'

Read at the Annual Meeting of the Southern Minnesota Medical Association, Austin, Minnesota, September 8, 1952.

The hydrocortisone acetate used in this study was supplied by Merck & Co., Inc., Rahway, New Jersey.

Dr. E. D. Henderson is with the Section of Orthopedic Surgery, Mayo Clinic, and Dr. C. C. Henderson is a Fellow in Surgery, Mayo Foundation, University of Minnesota, Rochester, Minnesota.

TABLE I. COMPOUND F IN THE TREATMENT OF POSTTRAUMATIC BURSITIS OF THE KNEE AND ELBOW

Case	Age	Sex	Site of Bursitis	History of Injury	Duration of Bursitis, Days	Fluid Aspirated		Dose of Compound F, mg.	Response	
						Cc.	Color		Degree*	Duration when Last Observed, Weeks
1	64	F	Olecranon	Yes	21	10	Red	12.5	4	16
2	52	M	Prepatellar	Yes	42	4	Red	12.5	4	15
3	52	M	Olecranon	Yes	?	10	Red	25	4	13
4	54	F	Prepatellar	Yes	10	8	Brown	12.5	4 (Recurred)	6
5	43	F	Pretibial	No	10	4	Yellow, clear	12.5 (on 3 occasions)	0	None
6	53	F	Olecranon	Yes	28	7	Red	12.5	4	6
7	20	F	Prepatellar	Yes	21	0		37.5	4	5
8	52	M	Prepatellar	Yes	42	2	Red	37.5	4	4
9	35	M	Prepatellar	Yes	14	4	Red	12.5	4	4
10	34	M	Prepatellar	Yes	4	0	Red	37.5	2 (swelling)	2
11	30	M	Prepatellar	No	6	0	Red	37.5	4	2
12	52	M	Prepatellar	Yes	5	60	Red	37.5	3 (swelling)	2
13	64	M	Prepatellar	Yes	6	15	Yellow, clear	25	4	12 days
14	40	M	Prepatellar	Yes	98	0		12.5	4	12 days
15	62	M	Olecranon	No	56	0	Red	25	4	9 days

*Rated on a basis of 0 to 4, 0 representing no response and 4 representing maximal response.

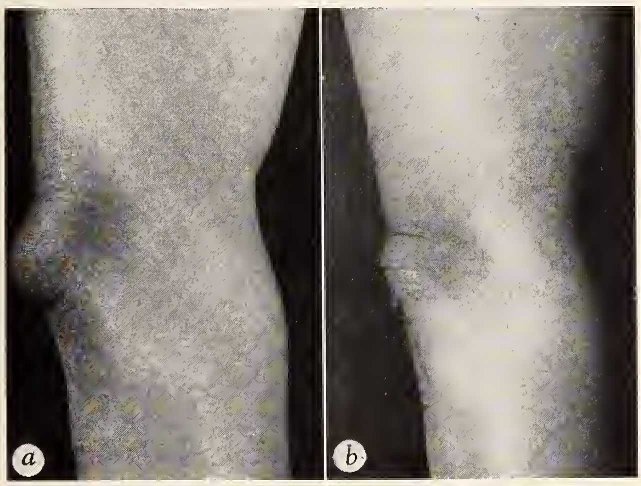

Fig. 2*a* and *b*. Olecranon bursitis of the right elbow before and nine days after injection of compound F.

duration; the swelling had followed a fall on the ice (Fig. 2). A fluctuant tumor was diagnosed as a manifestation of olecranon bursitis and the technique outlined in Case 4 was carried out as an office procedure. The bursa was evacuated of 7 cc. of brownish-red fluid, and 12.5 mg. of compound F in a volume of 0.5 cc. was injected. The patient was improved several hours later and she has remained free of pain or swelling to this date, a period of six weeks. She stated that now the elbows look alike.

The thirteen other patients were treated in a manner similar to that used in Cases 4 and 6.

Of the total series of fifteen patients, ten with prepatellar bursitis and four with olecranon bursitis experienced striking improvement within twenty-four hours and complete relief of symptoms to date with the exception of the patient in Case 4, who had a recurrence of prepatellar bursitis following continuing trauma. The remaining patient is a woman with pretibial bursitis, the bursa overlying the tibial tubercle. There was no history of injury and the bursa contained a clear, yellow fluid. Three separate aspirations followed by injection of compound F failed to effect a cure and the bursa was then excised surgically.

In the thirteen patients in whom unequivocally good results were obtained the dose of compound F varied from 12.5 to 37.5 mg. with no detectable difference in the results. The bursitis responded just as rapidly and completely with the smaller amount as with the larger amount of compound F. Ten bursae were aspirated of their fluid and eight of these contained reddish or brownish fluid, showing the presence of fresh or old blood. Two of the bursae contained a clear, yellow fluid, the condition of one of which failed to respond to the injection of compound F. Five of the bursae were not evacuated, but from three of these enough fluid was aspirated to determine that it was reddish; the condition of all five of these bursae responded rapidly to the injection of compound F as evidenced by prompt and complete disappearance of the tumor. In all the patients in whom the bursitis responded favorably to treatment, the amount of fluid in the bursa steadily decreased in amount, some within twenty-four hours and all within a week.

Comment

There is evidence to support the supposition that compound F is maintained in effective concentrations within the bursal sac for at least several days. In the five patients in whom the fluid was not aspirated prior to injection of the hormone, there was a gradual decrease in the amount of fluid over a period of four or five days. In three of the patients in whom the bursa was aspirated there was a moderate recurrence of the fluid within twenty-four hours, but this fluid gradually disappeared in the next few days.

Aspiration of the bursae and injection of compound F were done as an office procedure in several of the cases presented. The procedure can be done easily with careful attention to aseptic technique and with local anesthesia or with no anesthesia at all. This is in contrast to the trouble and expense and the not infrequent complications involved in the surgical excision of these bursae. It also has obvious advantages over the method of repeated aspirations followed by the use of pressure dressings. The latter method is frequently unsuccessful in spite of persistence of the treatment.

It would seem desirable to limit the use of compound F to those cases of bursitis in which either a history of injury or the presence of blood-stained fluid in the bursa indicates that the condition is of traumatic origin. If frank pus is obtained on aspiration or if true infectious bursitis is present, compound F is probably best withheld. Redness around the bursa may mean only inflammation and not necessarily infection.

A dose of 12.5 mg. of compound F seems to be adequate in all cases, although a large unaspirated bursa could conceivably require twice or three times this dose to produce the desired effect.

Compound F in the dose used seems to have no systemic effects and there have been no complications of this treatment to date.

Summary

Fifteen patients with posttraumatic (noninfectious) bursitis of the knee and elbow have been treated with a local injection of compound F in the past four months at the Mayo Clinic. One patient did not experience a beneficial effect and another had a recurrence of symptoms. The remaining thirteen demonstrated striking and lasting improvement. In the latter group the inflammation and tenderness subsided in twenty-four hours and the effusion disappeared and has not returned.

FRIEDLANDER'S PNEUMONIA

(Continued from Page 136)

Summary

While of infrequent occurrence, Friedlander's pneumonia is nevertheless an important and serious disease. It has a high mortality rate, a high incidence of complications, and requires specific therapy. It is considered of paramount importance to emphasize, therefore, the necessity for a careful differential diagnosis in acute pulmonary infections.

SENILE NODULAR THYROPATHY

HAROLD H. JOFFE, M.D.
Duluth, Minnesota

THE FAMILIAR signs and symptoms of frank hyperthyroidism are frequently absent in the elderly patient with a toxic nodular goiter. The terms "masked hyperthyroidism, goiter heart and thyrocardiacs" have been used to designate the group of patients with toxic nodular goiters in whom the classical clinical picture of hyperthyroidism is replaced by cardiovascular symptoms such as: dyspnea, weakness, weight loss, congestive heart failure, auricular fibrillation and/or palpitation.[1,2,5,6,7,16,18,22,23] It is in this group that the underlying remediable cause is frequently either undiagnosed with resultant death or diagnosed too late so that the cardiovascular damage is irreversible.

The purpose of this paper is to review (1) ten instances of cardiovascular deaths with necropsy from 1937 through 1951 resulting from undiagnosed nodular goiter; and (2) review histories of thirty-one patients with nodular goiter discovered out of 227 thyroidectomies, during this same period, in people over fifty years of age in whom the outstanding clinical symptoms were of a cardiovascular nature. These groups will be designated as I and II, respectively. None of the patients exhibited hypertension, coronary and/ organic heart disease.

Symptoms

The sex ratio was two to one in favor of females in one reported series of twelve cases.[7] In our combined group of forty-one cases, the ratio of females to males was 4.5 to 1. The average age was 62.8 years in two series reported elsewhere totaling thirty-four cases[7,18] as compared to 63.9 years in our series. In the same two series the symptoms of weight loss, dyspnea, congestive heart failure and auricular fibrillation, occurred in that order of frequency. In our group (Table I), the outstanding signs and symptoms were auricular fibrillation in 77.2 per cent; dyspnea 65.7 per cent; palpitation 51.2 per cent; pedal edema 42.8 per cent; weight loss 40 per cent; weakness 34.2 per cent; cough 28.5 per cent; albuminuria and palpable liver in 25.7 per cent each. The duration of symptoms varied from four to forty-two years in one series of twenty-two surgical cases.[18] In our Group I, the duration of symptoms ranged from two months to fifteen years with an average of 3.5 years as compared to six months to twelve years with an average of 1.4 years in Group II.

TABLE I. SYMPTOMS*

Symptom	Number	Percentage
Auricular fibrillation	27	77.2
Dyspnea	23	65.7
Palpitation	18	51.2
Pedal edema	15	42.8
Weight loss	14	40.0
Weakness	12	34.2
Cough	10	28.5
Albuminuria**	9	25.7
Palpable liver	9	25.7

*Six patients in Group II had insufficient data.
**Two plus or more.

Pathology

The almost uniform absence of hyperplasia and lack of knowledge regarding the biochemical nature of the secretion, makes it impossible to postulate as to the pathogenesis of the thyrotoxicosis.[9,21] The gland is usually enlarged but may be small. In our series of thirty-five cases, the thyroid was palpable in twenty-seven or 77.2 per cent. In Group I, the weight of the gland ranged from 72 to 210 gm. with an average weight of 131.7. The heart weights ranged from 310 to 440 gm. with an average of 358 gm. There was no correlation between gland size and heart weight. In Group II, subtotal thyroidectomies, the weight of the gland ranged from 10 to 157 gm. with an average of 75.1 gm.

The variation in the size of the acini with cystic acinar, colloid and epithelial degeneration, absence of hyperplasia and interstitial fibrosis are the outstanding histopathologic features.[9,18,19,21] The presence of an occasional area of hyperplasia in a predominate picture of degeneration may signify either recent stimulation or previous hyperactivity.[21] The constant finding of poorly staining colloid which assumes a basophilic character is be-

---

Presented at the Interurban Academy of Medicine Meeting, Duluth, Minnesota, on September 17, 1952.

TABLE II. CAUSE OF DEATH

Mode	Number	Percentage
Congestive Heart Failure	5	50
Embolic		
Femoral	2	20
Axillary	1	10
Cerebral	1	10
Pulmonary	1	10

lieved to be an altered secretion of a degenerative process and the basis for the thyrotoxicosis.[9,21]

A histologic review of our series revealed no single diagnostic criterion. The variation in the acini with cystic degeneration, flattening of the epithelium, absence of hyperplasia, poor staining colloid with basophilic tendency and interstitial fibrosis was a constant finding but is not pathognomonic of this definite clinical entity.

The mode of death in our series (Table II) was either pure congestive heart failure or an embolic episode.

Diagnosis

The willingness to accept the more common explanation for the cardiac disability, such as arteriosclerotic heart disease and/or coronary insufficiency, not only decreases the diagnostic acumen but limits the therapeutic possibilities for a remediable condition.[2]

Thyrotoxicosis should be suspected in all elderly patients with auricular fibrillation who fail to respond to the accepted form of therapy.[2,3,6,8,14,18,22,24,25,29] In a combined series of 805 cases of nodular goiter, auricular fibrillation occurred in 14 per cent of the cases.[8,25,29] A review of 2,958 cases of auricular fibrillation in the literature[14] revealed the presence of thyroid disease in about 9 per cent. This inefficient type of rhythm is present in 85 per cent of all cases of congestive heart failure associated with hyperthyroidism and is the major factor in the production of congestive heart failure in thyroid disease.[22]

The absence of the classical symptoms of hyperthyroidism is a characteristic feature. The fallacy that an increased basal metabolic rate is an essential diagnostic criterion adds to the pitfalls of an inaccurate diagnosis. The basal metabolic rate is often normal or only slightly elevated. In a series[18] of twenty-two toxic nodular goiters, the basal metabolic rate varied from a minus twelve to a plus forty-two with an average of plus twenty-eight. In a group of seventy nodular and thirty diffuse goiters with clinical evidence of thyrotoxicosis, the basal metabolic rate ranged from a minus five to a plus nineteen in 78 per cent of the cases.[9] In our Group II (Table III), the range was from minus fifteen to a plus seventy-nine with an average of plus 26.9.

TABLE III. BASAL METABOLIC RATE*

B.M.R.	Number	Percentage
—15	1	3.6
+ 5 to 10	2	7.2
+11 to 20	9	32.1
+21 to 30	8	28.5
+31 to 40	4	14.0
+41 to 50	2	7.2
over 50	2	7.2

*Not available in three patients.

A decreased circulation time, which is affected by anemia, fever, B avitaminosis and congestive heart failure, may be suggestive of hyperthyroidism but is not diagnostic. A therapeutic trial with Lugol's has the disadvantage of a lengthy period of observation and delays the use of radioactive iodine.[6]

The plasma-protein-bound iodine is an accurate determination and a value greater than 8 μg. per cent is diagnostic. A simpler test is the determination of radioactive iodine uptake. In the presence of an adequate twenty-four hour urinary output, an excretion of less than 20 per cent is considered diagnostic of hyperthyroidism.[6] Since the accuracy of this test depends on completeness of urine collection and kidney function, a low excretion should be confirmed by the plasma-protein-bound iodine.

Treatment

The end result of all untreated toxic goiters is death from heart failure.[19] To wait until the cardiovascular injury is irreversible is wishful procrastination. Non-thyrotoxic congestive heart failure and angina pectoris have responded fairly well to total thyroidectomy.[4,10,11,12,15,22,26,27] In a followup series of 208 postoperative thyrocardiacs with auricular fibrillation and/or congestive heart failure,[22] normal rhythm was restored in 71.5 per cent; 27 per cent continued to fibrillate and 1.4 per cent were completely incapacitated because of heart failure. The success of subtotal thyroidectomy in nodular goiter with cardiovascular symptoms depends on the early recognition of the disorder before irreversible cardiac damage occurs.

Summary

1. Ten instances of cardiovascular deaths from unrecognized nodular goiter are reported.

2. The outstanding symptoms in order of frequency in the combined group of forty-one patients with nodular goiter were: auricular fibrillation, dyspnea, palpitation, pedal edema, weight loss, weakness and cough.

3. The variation in the acini with cystic degeneration, flattening of the epithelium, absence of hyperplasia, poor staining colloid with basophilic tendency and interstitial fibrosis were constant histopathologic findings.

4. The mode of death in Group I was equally divided between congestive heart failure and an embolic episode.

5. The basal metabolic rate ranged from a minus fifteen to a plus thirty in twenty or 71.4 per cent of the patients and is not a reliable diagnostic procedure.

6. The early recognition of this definite clinical entity would prevent irreversible cardiac damage and death from a missed diagnosed cardiovascular disease.

KEEP PLUGGING "YOUR DOCTOR" FILM

Local medical societies can improve their "public relations rating" in the community by booking the "Your Doctor" film for non-theatrical showings at society meetings or to PTAs, schools, churches and other groups interested in health. Sixteen milimeter prints of this fifteen-minute sound film now are available on loan from Modern Talking Picture Service, Inc., 45 Rockefeller Plaza, New York 20, N. Y. Produced as a documentary, this film points up ways in which the medical profession has helped to bring better medical care to everyone. During 1952 more than 12 million Americans viewed the movie in over 5,000 commercial theaters throughout the country. It is hoped that medical societies will continue to promote the film locally.

PHYSICAL SYMPTOMS OF DEPRESSION

WILLIAM S. CHALGREN, M.D., Ph.D.
Mankato, Minnesota

A DEPRESSION is a serious disease. It inflicts far more pain and discomfort than do most organic diseases or injuries. A depressed patient, like a leper, may suffer years of anguish and misery, avoiding family and friends, seeking refuge behind bars and finding peace only in death. Patient after patient has said, "I would rather suffer any other kind of illness than go on this way." The disease occurs at any age of adult life; the symptoms may last from weeks to years; repeated episodes are common and the outcome may be fatal in the form of suicide.

Are the above statements overly emphasized and dramatic? I think not, especially after seeing and treating a large number of these patients. One hundred case histories of patients whose illnesses were predominately that of depression were reviewed for this presentation. The patients were seen in Mankato over a period of the last two years. They come from the farms and small towns of southern Minnesota and northern Iowa. There were thirty-five males and sixty-five females. The age range was from eighteen to seventy-two years. Seventy-eight of the one hundred patients were between the ages of thirty and sixty. The duration of symptoms before referral ranged from one week to twenty years, There were twenty-three patients whose illnesses had been present one month or less and forty-six patients with symptoms three months or less. Twenty-seven patients had been sick for a year or more.

The incidence of previous depressions was high. Almost half the group, forty-six patients, had had one or more episodes before; nine of these had two previous episodes and seven of the group had three or more previous attacks of depression. It is interesting to note that nineteen of the twenty-three patients whose symptoms had been present a month or less had experienced previous episodes of depression. The fact that they had had a similar illness before perhaps led to their more prompt willingness to have psychiatric care. There were two suicides in the group, both males, aged fifty-two and seventy-two.

Before discussing the symptoms of depression it might be in order to define the disease. Three forms of depression are commonly recognized: the depressed phase of a manic-depressive psychosis, the involutional depression, and the depression with psychoneurosis, sometimes called neurotic or reactive depression. The first two are regarded as psychoses and as such are presumably more malignant and demanding of more heroic treatment. The neurotic depressions by implication are milder, non-psychotic, and responsive to psychotherapy. In many cases, however, it is difficult to draw a line between psychosis and neurosis, and we see many cases of neurotic depression that are far more severe than are some cases of psychotic depression. Suicide may occur in all groups. Response to electric shock and other therapy seems to depend on many factors, but not on whether the depression is a neurotic or psychotic variety. It is therefore becoming increasingly evident that the above diagnostic categories are artificial, and that the management of a depressive type of illness depends not upon some specific diagnosis but upon the circumstances and dynamics of each individual case.[1] If we do not use the above categories to define depression what criteria shall be used? One of the best definitions is, "the mental state of a person who is unhappy and who is ill with his unhappiness."[3] The key point of this definition is that the person is ill. It is this fact that brings the patient to the doctor for help. And it is the recognition of the symptoms of this illness that is the concern of this paper.

In reviewing the symptoms of the one hundred patients in this study it became apparent that the cases could be separated into three general groups. In one group the symptoms were chiefly emotional and mental, and physical symptoms of ill health were minimal. Forty-five of the one hundred cases were in this group. In a second group of patients the emotional and mental symptoms were equally prominent, but in addition there were many physical complaints. Thirty-four cases were in this category. In a final group the physical symptoms were prominent and there were few overt depressive symptoms. Twenty-one patients showed this picture.

Read at the Annual Meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 8, 1952.

Patients with predominately depressive symptoms and few physical symptoms.—There are many symptoms of depression which are obvious to everyone. The patient complains of being depressed, melancholy or blue. Crying spells are frequently present. The future appears hopeless. The patient feels worthless and "better off dead." He complains of loss of appetite and of an inability to sleep. His work is done with difficulty or not at all. He may be nervous and agitated. Guilt feelings, religious ruminations, paranoid feelings and irrational worries are frequent. The patient is usually afraid to be left alone, yet he will not leave the house. He may develop fears of harming himself or his family. Phobias and obsessions may occur. Often these patients will have few or no physical complaints except for the difficulty in sleeping and eating and an inability to work. The depressive elements of the illness overshadow minor physical symptoms. The patient often recognizes the functional nature of his illness and will say he is in good physical health. Of the one hundred cases studied, forty-five were in this group.

Case 1.—A single man, aged forty-seven, stated, "I have a bad case of melancholia." His present illness began nine months previously when he was given a new job involving more responsibility. He became depressed and quit. He cried at times. "Some days I just live on will power." He said he never felt better with respect to his physical health. He had had three prior depressions at the ages of fifteen, eighteen and twenty-three. The last one occurred at the time his mother died, and lasted three years. The patient was treated with intensive psychotherapy for a month. After an initial response he regressed and was hospitalized. After four electric shock treatments he recovered completely, and shortly thereafter returned to his new job.

Case 2.—A young married woman, aged twenty-three, with four children, complained, "I am afraid of something." Her illness began suddenly one month previously when she thought, "you are going to die young." After that she was afraid to be alone, cried frequently, became depressed, worried about sharp objects about the house and almost struck one of the children with a knife. She had no complaints about her health, though she did have several anxiety attacks at night. She had considerable difficulty in sleeping. Her past health had been good and there was no prior history of neurosis. She was seen in the office on a number of occasions and her symptoms disappeared with psychotherepy.

Case 3.—A married woman, aged fifty-six, no children, became depressed about a year previously. She developed a phobia about grease and washed dishes constantly. She had many guilt feelings over alleged sins. She cried frequently, she had occasional headaches and she complained of being tired, nervous and unable to use her mind. Her past health was good. Her menses had ceased about four years previously. After a series of electric shock treatments her phobias and depression disappeared. She has been well for over two years.

Patients with depressive symptoms and many physical symptoms.—Although we usually think of depression as an emotional and psychological illness, we know that such an illness occurs within the framework of our body. Psychosomatic medicine has taught us that all parts of this body are very sensitive to mental maladjustment. This is particularly true when the maladjustment is an emotional one. It is natural to expect then that a depressed patient will have many physical symptoms.[2] These physical symptoms can involve any organ and tissue of the body. In the present series disturbances of autonomic nerve function were most frequent, but voluntary nervous reactions were retarded as well. Pain was a most common complaint. It was localized anywhere. The patient frequently complained of pain and tight feelings in the head and back of the neck. The pain was sometimes in the eyes or ears, in the mouth, in the chest and abdomen. Often the pain was in the joints or in the muscles. Some patients said, "I have pains all over." The pains were intense or mild. They were steady or intermittent. They remained in one place or they changed locations. They were not imaginary. The patients suffered from them and were very grateful when they were relieved. Cranial nerve symptoms were frequent. They included many complaints regarding vision. Some patients had had repeated changes of glasses. Complaints of diplopia, dizzy spells, tinnitus and hearing loss were noted. A lump in the throat or a complaint of a difficulty in swallowing was frequently present.

Several patients complained of a tight feeling in the chest, of pain in the precordium or other parts of the chest, of palpitation, dyspnea, rapid heart action and inability to breath. These complaints often occurred as spells indistinguishable from anxiety attacks. We must remember that the depressed patient is an anxious patient, and many of his symptoms resemble those of an anxiety neurosis. Gastro-intestinal complaints were perhaps the most common of the physical symptoms seen in the present series of patients. Stomach pain, indigestion, an empty feeling in the epigastrium, constipation and diarrhea were frequent.

Some patients related these symptoms to their depression while others felt that they were suffering from some particular disease. Genito-urinary complaints included frequency and burning of urination, changes in the menstrual cycle, vaginal discharge, pain in the pelvic region and impotence. Many patients had general symptoms of fatigue and weakness. In two cases the complaint of hot and cold spells was prominent. Two cases of generalized dermatitis were associated with depression. Frequently the presence of these physical complaints plus the anxiety plus the depression caused many patients to interpret these symptoms as evidence that they had some incurable disease or that they were going to die. A particular symptom that has appeared in many of these patients is a sense of tightness, heaviness or constriction which is localized in the mid-line of the body anywhere from the throat to the epigastrium. It is a symptom which is very distressing to the patient. In several patients it has served as an accurate barometer of their illness, remaining as long as the patient showed any signs of depression.

The physical symptoms as listed above were prominent in fifty-five of the 100 patients studied. In thirty-four of the patients the psychological symptoms of depression were also prominent, and it was obvious in talking with the patient that the main problem was one of depression.

Case 4.—A young married woman aged twenty-six, with two children, stated, "I'm depressed all the time." Her present illness began two months previously. She made a suicidal attempt after an argument with her husband. She herself felt she had been depressed for over two years. She had severe joint pains and worried that she would be deformed with arthritis. She had many headaches. Past history revealed that she had had several prior episodes of feeling depressed. Several family members had been depressed, and there had been three suicides in the family. A diagnosis of psychoneurosis was made elsewhere and she was sent to me for psychotherapy. She failed to respond to such a program, but her symptoms disappeared after a series of electric shock treatments.

Case 5.—A man, aged sixty-four, complained of chronic "stomach pain" since a partial bowel resection twenty-eight years previously. In the last six months the distress became worse, and six weeks before referral an ulcer was diagnosed. The patient then became increasingly agitated to the point where he could not eat or sleep or do any work, make decisions, et cetera. He cried frequently. History brought out that he had retired from his farm nine months before and that he had become more and more restless since. He recovered completely after a series of shock treatments, had no physical complaints, and resumed work on the farm.

Case 6.—A woman, aged forty-eight, complained of nervousness ("I can't even sit still"), palpitation, a funny feeling in her head, eyes and neck, insomnia, fifteen-pound weight loss and depressed spirits. These symptoms came on suddenly two months before, for no apparent reason. The patient had a similar but more severe episode nine years before, relieved by Metrazol treatments. A mild recurrence developed four years ago. After a short program of office therapy her spirits improved, her symptoms disappeared and she felt she had recovered.

Patients with predominately physical symptoms and few depressive symptoms.—In twenty-one of the one hundred cases the physical symptoms of the patients' illness were emphasized and underlying depressive features were masked by the patient's complaints and his concern about them. There are many cases of mild depression in which the basic nature of the disease is concealed by the accompanying physical symptoms. Many of these patients recover either spontaneously or after the reassurance of a physical examination and of some treatment to the major physical symptoms. In some cases the treatment of the physical symptoms alters the patient's environment which in turn results in an improvement of the depression. Some of these patients are cured by faith-healers, chiropractors, changes within the family, et cetera. In some patients the depression continues and more definitive therapy becomes necessary.

Case 7.—A man, aged twenty-seven, stated his complaints as "numerous." Six months previously he developed a weakness in his legs. Later he developed pain which moved from his back to his shoulders, to his knees, et cetera. He complained of difficulty in swallowing and talking. He felt he had a clumsiness of the fingers. He had photophobia, tinnitus, dizzy spells, poor memory and a fear that he was suffering from an incurable disease. He had been referred because of possible multiple sclerosis. He admitted that he was depressed and said he had been so for about two years. He had a number of guilt feelings about his Army experiences since most of his time in the Service was spent as a student. His past health had been reasonably good except for possible pericardial effusion at the age of seven. The patient was seen over a relatively long period of time and given psychotherapy. His physical symptoms disappeared but he remained depressed. He was finally hospitalized and was given six electric shock treatments. He made a remarkable recovery and felt completely well.

Case 8.—A married woman, aged fifty-two, with no children, stated, "This is the fourth time I have had this nervous trouble." Her present episode started five months previously with a "kidney infection." She also had pains in her stomach, backache, headaches, and a funny feeling in her throat. She was referred to me by a laryngologist whom she had seen several times for her throat difficulty. Twenty-three years previously she developed abdominal pain. She went to several doctors and finally had an exploratory operation. Following this she was nervous for nine months. She was very restless, she cried, and she lost interest in everything. She finally recovered and went back to work. Ten years later she developed pain in her flanks after her husband had been called out of town. Again she became quite nervous and depressed. This illness lasted several months. Two years ago she suddenly developed pain in her chest. She was quite nervous and agitated. This illness lasted about five months. During her present illness she lost interest in everything. She felt quite depressed, she had difficulty in eating and sleeping and she went to several doctors for help. She was treated by me in the office with only moderate success. She was finally hospitalized and given electric shock treatments with considerable improvement. She had more energy and many of her complaints disappeared. She still worried about some disease in her throat.

Case 9.—A man, aged fifty-four, complained of pain in the head and neck, of an upset stomach, abdominal pain, soreness and burning of the mouth, pains in the chest, dizzy spells, sensitivity to noise and inability to work. These complaints developed about eighteen months previously. During much of that time he doctored for his stomach complaints. His illness was accompanied by some depression. He admitted that he cried frequently and that he felt blue much of the time. His past health had been good. Three years previously he had suffered from a ruptured intervertebral disc which was cured with conservative management. The patient was seen in in the office on a number of occasions. Certain changes were made in his work and he gradually responded to a program of reassurance and psychotherapy. As his spirits changed his symptoms disappeared.

Discussion.—One ordinarily thinks of a patient suffering from a depression as a patient who is melancholy, who is retarded in his thinking and actions, who often has feelings of guilt and of unworthiness and who talks of suicide. It is not emphasized that the above feelings are usually accompanied by many physical complaints, yet it is usually the physical complaints that bring the patient to the doctor. In over one-half of the one hundred cases studied there were various specific physical symptoms, and in one-fifth of the cases the physical symptoms masked the underlying depression. Several of the patients in this study were referred because of a specific physical complaint although, of course, the referring physician recognized the functional origin. In case seven for example the patient was referred to rule out multiple sclerosis. Two patients were referred because of impotence. Another patient was referred because he had lost the use of his left hand. Several of these patients had had operations during the course of their depressive illnesses. This is not unusual since patients with depressions may seek surgery in an effort to alleviate their discomfort. Many of the physical symptoms were of a neurotic or hypochondriacal nature, reflecting anxiety. We must remember that anxiety itself is a symptom of depression. In other cases the basic depression is accompanied by a general slowing of bodily function, especially that controlled by the autonomic nervous system. The patient naturally relates his illness to his physical symptoms, thus diverting his own and his physician's attention from the real condition. When the physician's history and examination indicate that the patient's complaints are functional in origin, he should make inquiry as to the possible presence of an underlying depression. Symptoms of a mood disorder will often be revealed with specific questioning. In some cases it will be difficult to decide whether the picture is one of a depression with neurotic features or of a neurosis with some depressive features. In general a depression occurs as a specific event with a definite onset and a definite change in personality, while a neurosis is more apt to be of indefinite origin and duration, and with no dramatic change from health to illness. It is important that the distinction be made, since, in case the illness is one of depression, it may be possible to effect a dramatic improvement with shock therapy.

Summary.—A depression is a malignant disease. Few diseases cause more suffering. Many cases are accompanied by a variety of physical symptoms. In some cases the physical complaints may mask the underlying depression. This may occur in either the psychotic or neurotic depression. Since shock therapy may achieve remarkable results in this disease, it is important to recognize its many features.

HERPES ZOSTER WITH MOTOR PARALYSIS

T. PAUL BLANSHARD, M.D., M.R.C.P.

Minneapolis, Minnesota

HERPES Zoster with motor involvement is sufficiently well annotated to need no more than passing comment. It may involve the cranial nerves, as in the well known Ramsey-Hunt syndrome (geniculate herpes), or the muscles of the trunk or extremities. Involvement of the abdominal wall was recorded by Taylor (1895) and recently there has been a discussion of such a case by De Dominicis (1951). Three examples of paralysis of the abdominal wall are recorded in the present report; in one the surgeon discerned the nature of the lesion and an operation was avoided, in another the protruding musculature was thought to be an abscess and aspiration was attempted.

Case 1.—S. B., a housewife, aged seventy-two years, was admitted to Fulham Hospital, London, in December 1946 on the recommendation of her local physician, who thought she might have intestinal obstruction. Five days prior to admission she had developed left sided abdominal pain which had persisted and was accompanied by vomiting. The bowels had not moved for three days until relieved by an enema just before admission to the hospital. She was a well-nourished patient who exhibited an extensive herpes zoster on the left side involving the tenth, eleventh, and twelfth thoracic segments. There was a marked resonant bulge in the lower left abdomen and paralysis of the musculature of the left side of the lower abdominal wall. The bulge was greatly accentuated by coughing. A recent photograph (Fig. 1) shows that the paralysis persists.

Case 2 (U. H. No. 824429).—J. N. K., a man aged sixty-five years, was admitted to University Hospitals, Minneapolis, in December 1950 with a diagnosis of hypertensive cardiovascular disease, coronary insufficiency and heart failure. One month prior to admission he had suffered a herpes zoster involving the lower thoracic nerves on the right. On examination in the hospital, paralysis of the lower part of the abdominal wall on the right side was observed.

Case 3 (U. H. No. 837761).—I. L. was a housewife, aged seventy-four years. This patient was referred to the Out-Patient Clinic of the University Hospitals, Minneapolis, in October 1951 for diagnosis of a mass in the right upper quadrant. She had had her gallbladder removed in 1915. Seven months prior to admission to the clinic she had developed herpes zoster in the region of the seventh thoracic segment on the right. Following this, a severe grinding pain developed in the right upper quadrant and an exploratory laparotomy was done a month later. The only abnormality found was a dilated common bile duct for which T-tube drainage was instituted and continued for two months. After operation a swelling of the right upper quadrant was noted and needled in the belief that it was an abscess. She was a well-nourished anxious woman. There was a bulging of the musculature of the upper part of the abdominal wall on the right, a bulging in no way related to operative scars. This was accentuated by straining. The scarring from the herpes was present and there was marked hyperesthesia of the involved skin.

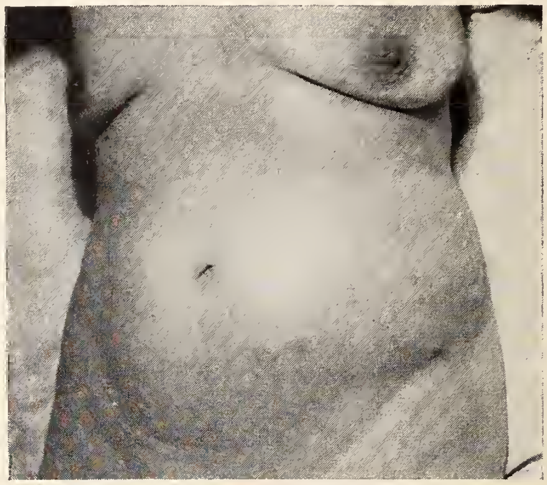

Fig. 1

The failure to diagnose *case 3* is understandable if the relationship between the onset of the rash and motor paralysis is not duly appreciated. In 25 per cent motor involvement may precede the eruption; in the remainder the interval between the rash and muscular paralysis may vary from a day to as much as two months (Taterka and O'Sullivan 1943). As far as the abdominal muscles are concerned paralysis is usually permanent.

Summary

Three cases of herpes zoster are reported with involvement of the anterior horn cells and in which the abdominal muscles were paralyzed. In all three the paralysis was permanent. The time relationship between the onset of the rash and that of motor involvement is briefly discussed.

Case Report

PERFORATED INTERVENTRICULAR SEPTUM

Report of Case

DAVID V. SHARP, M.D.
Minneapolis, Minnesota

THE patient was a sixty-seven-year-old white male. On the morning of April 28, 1952, he experienced a sudden, severe substernal pain while sweeping his attic floor. He became extremely weak, began to perspire profusely and walked downstairs to his room to lie down. Whiskey and aspirin failed to give relief. The pain persisted until he experienced a sense of tightness and constriction to the point of anxiety and fear. The pain radiated down the arm to the right elbow and around the chest. The patient was immediately sent by ambulance to the hospital. After reaching the hospital, the patient had a small emesis and felt somewhat improved. The narcotic given only dulled the severe precordial pain which radiated along both arms accompanied by a sense of suffocation and breathlessness. His whole body was drenched with perspiration and he was immediately placed on the critical list.

There was no past history of hypertension. A minimal anginal syndrome had been present on effort and he had experienced slight cramps in his legs on walking rapidly. The patient's initial examination revealed him to be in shock and perspiring profusely. He was pale and slightly cyanotic while in oxygen. The pulse rate was forty-eight per minute, strong but irregular with no definite pattern. The electrocardiogram pulse was sixty per minute. The pupils were regular and equal. No thrills were noted on palpitation of the precordium. Heart sounds were of fairly good quality. The aortic second sound was louder than the pulmonary second. The blood pressure was 154/80 mm. Hg. The remainder of the physical examination proved to be essentially negative.

At approximately 5 p.m., auscultation revealed a loud systolic murmur to the left of the sternum. The pulse became more rapid and of poorer quality. The blood pressure tones heard below the cuff revealed unequal impulses and the pressure began to drop rapidly. The temperature began to rise somewhat from shock levels. There were two emeses of clear liquid. No such systolic murmur had been noted on admission.

The patient was given dicumerol, and prothrombin times were kept at a level of 25 to 35 per cent, except on May 7, when his prothrombin time suddenly dropped to 10 per cent and then rose to 23 per cent on the following day prior to death.

Clinical Course.—At no time during his hospital residence of eleven days did the patient satisfactorily improve his condition of shock. The blood pressure leveled out to approximately 100/50 mm. Hg. for five days prior to death. The pulse ranged between eighty and 100 and was of poor quality. His pain gradually subsided, and no narcotic was necessary after the fifth day in the hospital. About this time the patient began to expectorate thin bloody sputum. No other physical evidence of pulmonary disease was noted; the patient's respiratory rate was twenty, easy and not labored. The loud systolic murmur to the left of the sternum persisted and carried over into the early diastolic phase. A slight icteric tinge to the sclerae was noted on the seventh day after admission.

On the eleventh day in the hospital the patient suddenly became dyspneic and expired.

Laboratory Admission Work.—Blood: hemoglobin 109 per cent; red blood count, 5,020,000; white blood count, 16,750; neutrophils, 81 per cent; eosinophils, 1 per cent; basophils, 1 per cent; lymphocytes, 16; monocytes, 1 per cent.

Urine: amber, specific gravity, 1025; acid; faint trace of albumin; no sugar, and 4-5 red blood cells to field.

On May 8 the sedimentation rate, one day before death, was 50 mm. in one hour. An electrocardiogram taken on April 28, revealed myocardial infarcation of the anterior coronary thrombosis type.

Discussion.—Loud systolic murmurs occurring after coronary thrombosis may indicate rupture of a papillary muscle, ventricular aneurysm, or a perforated interventricular septum.

Perforated interventricular septum is usually characterized by a precordial systolic thrill and a loud murmur following an acute thrombosis. Location of the thrill and murmur is usually in the fourth or fifth interspace to the left of the sternum. The murmurs may be harsh and widely transmitted. This remains prominent despite weakening of other cardiac sounds. With a larger septal defect, a diastolic murmur is also heard, but this may also be evidence of a ventricular aneurysm. In rupture of an infarcted papillary muscle the thrill is usually absent, whereas the thrill is present in over 50 per cent of ruptured interventricular septa. In the former condition a murmur is usually heard at the apex and not along the left border of the septum. Occasionally circulatory collapse may eliminate the anticipated physical signs. The electrocardiogram is of importance in the diagnosis of coronary thrombosis, but of little value in the diagnosis of a perforated interventricular septum as the location is usually low in the septum.

Edmonson and Hoxie[1] in reporting thirteen cases, stated that they believe rupture of the heart is most likely to occur in those patients with persistent hypertension after infarction. Perforation almost always occurs within seven days of the onset of the coronary thrombosis. Few patients live longer than a month after perforation. One of thirty-six patients reported by Wood and Livezy[2] survived almost five years.

Seventy-seven cases of perforation of an infarcted interventricular septum have been reported; in twenty-nine, the diagnosis was made before death. This is probably the thirtieth case in which a diagnosis before death was made, and the seventy-eighth since the report by Zucker et al.[3]

Other pertinent autopsy data noted by Dr. H. Sanford, Pathologist of Asbury Hospital, Minneapolis, are as follows:

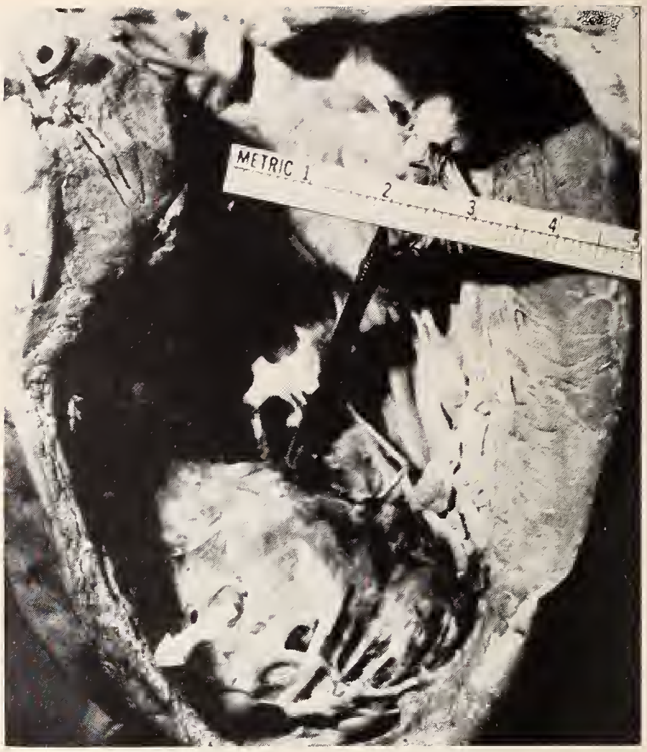

Fig. 1. (a) Perforation of interventricular septum—see forceps extending through perforation, and (b) aneurysm of ventricle (see arrow).

Thrombosis, anterior descending branch, left coronary artery.

Infarction, anterior wall, left ventricle.

Generalized arteriosclerosis: Coronary arteries, moderately severe; aorata, moderately severe; kidneys, moderate.

Atelectasis.

Chronic passive congestion, liver, spleen, kidneys, lungs.

Pericardial adhesion, anterior.

This case is interesting, not only in that an ante mortem diagnosis of perforated interventricular septum was made, but also for the presence of an aneurysm of the ventricle resulting from an anterior coronary thrombosis.

SULFOBROMOPHTHALEIN TEST OF LIVER FUNCTION

CHARLES A. OWEN, JR., M.D.

Rochester, Minnesota

THE sulfobromopthalein test of hepatic function needs no defense; it has been reported to be positive in miscellaneous hepatic diseases, particularly cirrhosis, in more than 90 per cent of cases. Also, retention of dye occurs surprisingly often in malignant disease of the liver.

Derivatives of phenolphthalein are cleared from the blood to some extent by way of the kidneys. The addition of a halogen to the molecule reduces renal excretion; the dye is then removed from the blood by the liver and is released into the duodenum through the biliary tract. The first dye used to study the function of the liver, phenoltetrachlorphthalein, leaves the blood stream slowly; in order to measure its biliary excretion stools were collected for forty-eight hours and assayed for the dye.

In 1924, Rosenthal and White found that sulfonating the halogenated phthaleins increased the rate of their disappearance from the blood; the compounds with bromine or chlorine disappeared faster than the derivatives of iodine. In animals the chlorinated dye appeared in the urine. Therefore, they chose the brominated derivative; their work led to the wide acceptance of phenoltetrabromophthalein sodium sulfonate, often called sulfobromophthalein (bromsulphalein).*

The original technique consisted of the intravenous injection of 2 mg. of sulfobromophthalein per kilogram of body weight. Thirty minutes later a sample of venous blood was withdrawn and allowed to clot; the serum was alkalinized and the presence of a reddish-purple color indicated retention of dye in the blood. The concentration of dye was determined by visual comparison with a series of standard colors. Absence of dye in the serum signified satisfactory hepatic function.

This method obviously is valid only if the clearance of dye is a function of the liver alone. Two observations support this contention: (1) in cases of biliary fistula 90 per cent of injected sulfobromophthalein appears in the externally draining bile within an hour and (2) in animals whose livers have been extirpated, disappearance of intravenously administered dye from the blood is extremely slow. The dog, unlike man, loses some of the brominated dye through the kidneys.

If the principle of the dye test is accepted as valid, the problem of dosage arises. This in turn depends on the speed with which sulfobromophthalein is cleared from the blood. It has been found that 2 mg. of dye per kilogram of body weight is cleared completely by normal persons in ten to eighteen minutes; 5 mg. of dye per kilogram is cleared in fourteen to forty-five minutes, with an average of about thirty minutes; 6 mg. of dye per kilogram is cleared in about thirty-five minutes and 10 mg. of dye per kilogram in about sixty minutes on the average.

The goal of this test, as well as any other laboratory procedure, is maximal sensitivity and a minimal number of false positive results. In the case of the sulfobromophthalein test the goals are somewhat incompatible. Thus, with a dose of 5 mg. of dye per kilogram of body weight and an allowance of only thirty minutes for the liver to clear the dye, the method would be max-

---

From the Section of Clinical Pathology, Mayo Clinic, Rochester, Minnesota.

This report includes the opinion of several members of the Section of Clinical Pathology at the Mayo Clinic and is based on experience of many years with this test at the clinic. The author wishes to express appreciation to Drs. T. B. Magath, D. R. Mathieson and F. D. Mann for advice and assistance in the preparation of the report.

*Manufactured by Hynson, Westcott & Dunning, Inc., Baltimore, Maryland.

imally sensitive, but "positive" results would be obtained in a number of normal persons. At the Mayo Clinic the attitude is conservative; the dose of 5 mg. of dye per kilogram is used but a period of one hour is allowed before the residual concentration of dye in the blood is determined. As a result, false positive results are obtained but rarely, but an occasional case of early hepatic abnormality may be missed. Others who use this dye in amounts of 5 mg. per kilogram prefer an intermediate end point, namely, forty-five minutes. Use of readings at one hour is as well justified as use of readings at forty-five minutes. The former technique simplifies instruction and handling of the patient. Those who use the smaller dose of dye, 2 mg. per kilogram, usually prefer an interval of thirty minutes between injection of dye and collection of blood.

With the advent of photoelectric colorimeters and even spectrophotometers in the clinical laboratory some have discarded the naked-eye estimation of concentration of dye in serum and substituted these electric devices because of their apparent greater precision. Since a practiced observer can evaluate the concentration of dye to within 2 per cent, the need for mechanization in routine determinations has not been established.

It is commonly considered that in the presence of jaundice the sulfobromophthalein test is inaccurate because the presence of excessive bile pigment in the blood confuses the estimation of concentration of dye. The method is practically meaningless in the jaundiced patient but not because of technical difficulties. If the jaundice results from hepatic damage the liver cannot clear the dye from the blood; if the jaundice is secondary to biliary obstruction the dye cannot be disposed of by the bile and thus is retained in the circulation. As a result the test is almost invariably positive in the jaundiced patient and has no differential diagnostic value. Two recent studies may alter this somewhat gloomy outlook: (1) in complete biliary obstruction, dye is still demonstrable in the blood after three days, while it will have disappeared in that time in the case of primary hepatic damage; (2) Zieve's group has ingeniously correlated values for retention of sulfobromophthalein with concentrations of serum bilirubin, and has suggested differential diagnostic possibilities. Further study is warranted.

A new criticism of the test, particularly when the larger (5 mg. per kilogram) dose is employed, has recently appeared. A group at Temple University found that as the excreted dye enters the intestinal tract, traces find their way back to the blood stream. However, careful investigation of this possibility has shown that the reabsorption is so minute as to be unimportant in the routine diagnostic test.

As with any procedure requiring intravenous injection, problems tend to arise. Some of these are difficulty in entering certain veins, venipunctures in children and the occurrence of reactions. Not a single fatality has occurred because of administration of sulfobromophthalein at the Mayo Clinic, although the test has been performed more than 60,000 times. Local pain occurs when the irritating dye is accidentally injected outside the vein but no necrosis or sloughing has been observed. Occasionally abdominal or precordial pain, nausea, or dizziness may occur and rarely generalized reactions, such as urticaria or asthmatic wheezing, may be encountered. Sensitization to sulfobromophthalein has not been reported.

Four observations that simplify performance of the test should not be overlooked: (1) rapid injection of the dye, rather than the recommended slow rate of injection, prevents painful venospasms and in experience at the clinic has not led to reactions; (2) no syringe or needle that has ever contained the dye should be used for the withdrawal of blood because traces of adherent dye can produce apparently positive results in the test; (3) the blood for testing should be discharged from the syringe gently, and with the needle removed to prevent hemolysis, which obscures the dye and (4) milky serum makes estimation of the concentration of dye difficult or impossible. Furthermore, it is possible that the ingestion of some types of food may temporarily alter the excretion of dye. Therefore the patient must fast before and during the test.

The simplicity of the sulfobromophthalein test for hepatic function, its need for only the most elementary equipment and the stability of the dye are factors that recommend it for general use. The dye is available readily on a commercial basis, together with properly prepared standard colors for comparison. The only additional equipment needed includes needles and syringes, tubes for the serum, a small comparator block

President's Letter

A GOOD BEGINNING

Those of you who attended the County Officers' meeting of the Association, on January 17, saw the completion of one of the first and most important steps in a project initiated by the House of Delegates at the annual meeting in 1951.

I am speaking of the rural medical student scholarship award. The first recipient of the four-year scholarship was Richard L. Engwall of Winthrop, Minnesota. He will receive $1,000 each year for four years while he is in medical school.

Richard Engwall is well known in Winthrop and neighboring areas for his continuous activities in school, college, church and civic affairs. He was valedictorian of his high school class, was class president three years, helped organize and was president of the Student Council. He was interested in and took part in high school and college sports and music, singing in choral groups and receiving honors in sports.

This scholarship marks the beginning—the beginning of a different approach to the problem of maldistribution of physicians in the country.

During the height of the heated campaign against compulsory health insurance, there was little time to consider a positive approach to any of the nation's medical needs.

When the emergency began to subside, it was time to initiate a positive program of action—to show the people that doctors themselves were deeply concerned in solving medicine's problems for the good of the health of the people.

Recognizing the difficulty that rural communities are encountering in obtaining doctors, and, as one of the facets of our Minnesota program, the House of Delegates in 1951 authorized the Rural Scholarship Program. A subcommittee of the University Relations Committee worked out the details of the program and selected Richard Engwall as the first recipient. Each succeeding year will result in a new selection until we are supporting annually four young men who will locate in towns of under five thousand.

Admitting that this is only a partial answer to the problem of maldistribution, we think is a good beginning. It points a way for communities needing doctors to obtain them. As the facilities for the practice of good medicine are gradually improved in the rural areas, maldistribution may cease to be a major problem.

PANEL PRACTICE

THE ARTICLE "Inside the British Health Plan" by Dr. James Rogers Fox of Minneapolis is written from personal experience and portrays his impressions of the panel system in Britain.

Dr. Fox is a graduate of the University of Minnesota Medical School, received his intern training at Minneapolis General Hospital and since 1948 has been a member of the University of Minnesota Medical School faculty.

At the request of Dr. Verney of the University of Edinburgh staff and as a result of his contacts with visiting faculty members from the University of Minnesota Medical School, Dr. Fox was given an appointment as a visiting staff member at the Royal Infirmary of Edinburgh and at the University of Edinburgh. During his visit, he had personal experience as a specialist and as a general practitioner in the panel system.

Another article by Dr. Fox on his experiences with medical practice in a socialistic state appeared in the January issue of the *Hennepin County Medical Society Bulletin.*

We are violently opposed to Communism and are nearly as strongly opposed to Socialism. We believe that the mistakes of others should be publicized when it comes to nations as well as to individuals, even though such action may border on the realm of gossip. We have the opportunity of learning from the mistakes of others, as well as from our own mistakes. The experiences of Great Britain, Australia and New Zealand in government-provided medical care should have wide publicity, and then if we follow the lead of these countries we shall have no one to blame for our stupidity but ourselves. These countries have found their excursion into state medicine much more costly than was anticipated, opened the way to abuses and required modification of services rendered. Also, the quality of medical care suffered. We are, therefore, happy to be able to present Dr. Fox's article as another testimony to the manner in which Socialism works when applied to medical care.

GAMMA GLOBULIN IN POLIO

SOME progress has been made during the past two years in the field of polio research. The demonstration by Dr. Dorothy Horstman of the Yale Medical School and by Dr. David Bodian of Johns Hopkins that the polio virus can be demonstrated in the blood of monkeys four to six days after it has been ingested and that antibodies are developed during this brief period opens up new possibilities. In a few monkeys, sufficient antibodies were formed to prevent paralysis, while in others the amount was insufficient or too slow in forming to prevent nerve-cell injury. In some instances, it was found to take three to seven days for paralysis to appear after the virus had been demonstrated in the blood. If during this period a slightly increased amount of antibody was added to the blood, paralysis could be prevented.

If this same sequence of events occurs in humans, it might be possible to prevent paralysis in some cases. In 1951-52, the hypothesis was tested by Dr. William McD. Hammon, Professor of Epidemiology at the University of Pittsburgh Graduate School of Public Health. Half of some 55,000 children in Utah, Texas, and Iowa were given injections of gamma globulin, the other half being given an innocuous substitute. Of the series, twenty-six cases of paralysis occurred among those inoculated, whereas sixty-four occurred in the control group. Financing of the investigation was by the National Foundation for Infantile Paralysis, with gamma globulin supplied by the American Red Cross.

Gamma globulin is not new. It has been used for the prevention or modification of measles and for epidemic jaundice for a number of years. Gamma globulin and serum albumin, which is so valuable in the treatment of shock, are obtained from the same pooled blood which is an important consideration as it is important that the blood contain antibodies for the several polio strains.

In view of the above facts, it seems as though something of distinct value has eventually evolved in the prevention of paralysis from polio.

At the request of the Office of Defense Mobilization, the American Red Cross has signified its willingness to expand its production of gamma globulin for free distribution with the proviso that some other agency take the responsibility of distributing the product.

Inasmuch as it takes over a pint of blood to provide the gamma globulin for one injection and an injection loses its effectiveness after five weeks, the required expansion of the Red Cross Blood Banks will be terrific. The annual campaign which will be conducted as usual in March will ask the public for 93 million dollars, which includes a necessary increase of 7 million to provide for this expansion.

Vaccination against polio will have to be limited to epidemic areas which may mean 150 of the 3,000 counties in the country. It is estimated that 2 million children will be exposed this year and each child may require two inoculations. It may as well be appreciated by the public that it is impossible for the Red Cross to expand its facilities fast enough to provide the gamma globulin which will be requested or demanded by frantic parents. The amount made available ultimately will also be dependent on the generosity of the public in the matter of dollars and blood.

The proof of antibody formation to polio infection, and the fact that infection with polio virus is much more widespread than the number of paralytic cases indicates, rationalizes the use of gamma globulin in an effort to reduce the havoc caused by the disease. The practical demonstration of its effectiveness justifies the extension of its use. It is within the realm of possibility that a vaccine may be developed before very long which will produce an active and long-lasting immunity to the disease.

PUBLIC RELATIONS AND THE MEDICAL PROFESSION

ON November 30, 1952, the day preceding the opening of the AMA Clinical Session in Denver, the Public Relations Department of the AMA held an all-day session at the Shirley Savoy Hotel. This was the fifth yearly PR meeting held, and if attendance is any criterion, interest in the meeting has been progressively increasing from year to year.

Public relations will always demand consideration on the part of most industrial or professional groups including physicians, human nature being what it is. Such a momentous change as that about to take place in Washington will not relieve the medical profession of the need for improving its public relations. It cannot be emphasized too often that the individual physician has the opportunity of being the best possible public relations agent for the profession. A physician who gives his best to each patient and bears in mind the Golden Rule is doing his part to better the public relations of his profession.

County, state and national medical organizations can and are contributing to the betterment of public relations. In 1948, there were about sixty emergency call stations in the country. The number was increased to some 650 by 1952. The number of county societies having mediation committees (formerly grievance committees) is also on the increase.

At the Denver meeting emphasis was placed on the key position held by the office assistant. A skit put on by a group of University of Colorado actors was illustrative. Too often physicians know little of what goes on in their reception rooms. A few years ago the State Medical Association of Iowa employed a field worker to explain Blue Cross and Blue Shield forms to office assistants and to instruct them in such fundamentals as answering the telephone and greeting patients. The office assistant is in a position to establish the whole tone of the office for better or for worse. The AMA pamphlet entitled "Winning Ways with Patients" contains some valuable suggestions for office assistants.

The physician is in a position to better the public relations of the hospital. He can prepare the patient for the shock of the first hospital bill by explaining that the rate for the room does not cover all the services rendered by the hospital but that such items as operating room, laboratory, anesthesia, x-ray and private nursing are extra.

The hospital needs this help. One hears considerable criticism of the high cost of hospital care and comparison is made with the cost of a hotel room today. It is forgotten that meals brought to the patient's room are included in the room rate and that floor nursing care in some hospitals amounts to as high as 38 per cent of the overhead. Some 500 hospitals throughout the country have distributed the AMA pamphlet entitled, "Your Money's Worth in Health," to their patrons in the interest of better public relations.

It was startling to hear that a group of young doctors in a western state a few years ago had shown an antipathy towards the American Medical Association. What grievance, actual or imagined, they had we do not know. When we consider that the AMA is composed of the state medical associations which in turn comprise the county societies and that the officers of the AMA are the men chosen by the representatives of the state associations it is difficult to understand such a situation. The formation of the Students' American Medical Association should do much to direct the medical students in the way they should go. The medical student of today, to some extent, is exposed to socialistic influences by professors who, consciously or unconsciously, instill in their minds socialistic ideas in relation to medicine.

The few members of the profession who overcharge for their services, insist on payment in advance of an operation, fail to provide for night calls, make unnecessary professional calls, operate unnecessarily and otherwise violate the Golden Rule give a black eye to their profession and counteract, to a large degree, the esteem in which most members of the profession are held by the public.

DR. DUBLIN RETIRES

Dr. Louis I. Dublin, statistician of the Metropolitan Life Insurance Company, whose name has become almost synonymous with life insurance statistics, retired at the end of the year 1952 after forty-four years of service. He joined the company in 1909. Two years later he organized the Statistical Bureau and has been its chief ever since. His contributions on mortality, morbidity, longevity and other subjects have been invaluable to Life Insurance underwriting and administration.

Dr. Dublin's time was not entirely spent at a desk, working over figures. He served at times as president of the American Public Health Association and chairman of the Board of Directors of the American Museum of Health which created the Hall of Man in the New York World's Fair of 1939-40. Much of his time has also been devoted to other activities which include the Bureau of Census, the Public Health Service, the National Research Council, the American Cancer Society, the National Tuberculosis Association, the National Health Council, the New York Tuberculosis and Health Association, and the Welfare and Health Council of Greater New York.

In 1944, Dr. Dublin was granted temporary leave to devote his full time as Assistant to the Chairman of the American Red Cross in Washington. During World War I, he was a member of the commission of the American Red Cross which was sent to Italy and the Balkans. As a result of his visit to France in 1945, a comprehensive program of relief was carried out by the American Red Cross for the children of France.

Dr. Dublin possesses that rare combination of scholar and practical administrator. His writings have been voluminous. It is hoped that his contributions to the welfare of mankind will not terminate with his retirement from the Metropolitan, but will continue for many years.

AMERICAN MEDICAL ASSOCIATION

Summary, Clinical Session

Denver, Colorado, December 2-5, 1952

The House of Delegates convened Tuesday, December 2, in Denver, Colorado. After the preliminaries, including the invocation and the report of the Reference Committee on Credentials, Dr. James R. Reuling, presiding as Speaker for the first time, introduced Dr. Louis H. Bauer of New York, President of the American Medical Association, and the meeting got under way.

In his presidential address, Dr. Bauer noted that there appears to be less danger, now, than for a number of years, of general socialization of medicine in the United States. But he listed a series of tasks which must still be accomplished if the American system of medicine is to be preserved, including the following: (1) work with rural communities to establish adequate facilities for physicians; (2) see that good medical care for the indigent is available everywhere; (3) extend public health coverage to all areas now lacking it; (4) develop plans for care of the chronic invalid; (5) expand the voluntary insurance program to cover more persons and also to cover persons over sixty-five and those suffering from illness of long duration; (6) clean the house of medicine by discipline of unethical physicians; (7) see that the services of a physician are always available; (8) revitalize county medical societies to make them leaders in all community health projects; (9) indoctrinate newly trained physicians in traditions and ethics.

Following presentation of President-Elect Edward J. McCormick of Toledo, Ohio, of Mrs. Ralph Eusden, President of the Woman's Auxiliary and of Mr. Clifford Vernick of Tufts Medical College and Mr. Leland Hoar of the University of Oregon Medical School, both representatives of the Student American Medical Association, reports of the Secretary, Dr. George F. Lull, and the Chairman of the Board of Trustees, Dr. Dwight H. Murray, and reference committee reports were given. Recommendations on these and other resolutions and reports gave rise to the following discussions and enactments:

"Commercialism" Lashed

Appointment of a committee was ordered by the House to work with the Advisory Board on Medical Specialties on development of means to increase the number and distribution of general practitioners. President Bauer declared, as a preliminary to this action, that the present system of channeling men into specialties virtually prevents general practitioners from ever becoming specialists and thus keeps the number of doctors going as general practitioners into rural areas far short of the need. He suggested that general practice be established as one of the prerequisites for a majority of the special fields.

In response to Dr. Bauer's sharp criticism of what he termed "commercialism" in the practice of medicine, the House recommended that "state associations be adamant in disciplining unethical members, that they require more rigid ethical standards for membership, that medical schools provide training in the ethics and traditions of medicine and that the House go on record as thoroughly disapproving any business arrangement between pharmacists and physicians."

The Doctor Draft

After a stormy session in committee, the following position on the doctor draft law was adopted and approved without debate on the floor of the House. The Council on National Emergency Medical Service was instructed to continue to support legislation "to provide the number of medical officers required to care adequately for the health needs of the uniformed armed forces," but on these conditions:

1. Revision of physical requirements for medical officers so that physicians with physical defects will be placed on military duty with appropriate assignments.
2. Development of better recruitment methods by the Armed Forces for regular Medical Corps personnel.
3. Greater use of civilian doctors and hospital facilities for care of both military and non-military personnel.
4. More economical and efficient use of physicians in all government agencies.
5. Establishment of more uniform "conditions of service" among the several government agencies to put an end to "undue competition" for medical personnel.

Care of Civilian Dependents

Especially, the involuntary call-up of physicians for the care of civilian dependents of servicemen was hotly opposed in the debate on the doctor-draft. The Council on National Emergency Medical Service has consistently contended that too many military physicians are being used for the care of civilian dependents. The answer of the Armed Forces was that only 8 per cent of all in-patient care and 20 per cent of all out-patient treatments stem from care of dependents, although the Deputy Surgeon General of the Army admitted that "approximately 60 per cent of dependents of Army personnel are being so cared for." The military contends that it must provide care for dependents overseas and in isolated areas of the United States and that its research, intern and residency programs and recruitment appeals get much of their strength from the fact that all types of patients can be seen by military surgeons.

For Special Pay

Further action on the doctor draft took the form of a resolution urging the President of the United States to defer any call-up of Priority III physicians until Selective Service and the Department of Defense have completed call-up of all physicians in Priorities I and II, except for the occasional individual who is considered essential.

The House also re-affirmed its approval of the $100 special pay for physicians and dentists in the Armed Forces and urged an early meeting of state chairmen of advisory committees to get their thoughts on future doctor-draft legislation.

Medical Service for Veterans

The general question of medical care for veterans with non-service-connected disabilities was also warmly debated. Eventually, the recommendation of the Special Committee on Federal Medical Services, also known as the Martin-Henderson committee, was rejected. This recommendation called for new legislation limiting medical and hospital benefits for veterans in Veterans Administration facilities, to veterans with service-incurred or aggravated disabilities and veterans with tuberculosis and neurological conditions who are unable to pay for treatment.

Dr. Norman Booher, Vice Chairman of the National Rehabilitation Commission of the American Legion, said he believed that Public Law 312 defining eligibility for admission to Veterans' Hospitals should not be tampered with in Congress, though he also felt that there was entire agreement between the Legion and the medical profession as to the desirability of eliminating "chiselers." He believed there should be enforcement of the present law by administrative action rather than by new legislation. Dr. Joel T. Boone, medical director of the Veterans Administration, also felt that the House should not vote hurriedly on the recommendation.

As a result of the discussion, the House adopted a recommendation that the American Medical Association, the American Dental and Hospital Associations, the Veterans Administration and the Department of Defense should "sit down and try to reach reasonable conclusions for appropriate action from agreed upon data rather than to take any precipitate action now."

Other recommendations of the Martin-Henderson committee asking for congressional study as to whether provision of medical and hospitalization benefits for dependents of service personnel is a "proper and desirable emolument of military service" and endorsing the present policy of transferring seriously disabled service personnel from service hospitals to Veterans Administration installations, were accepted.

Care for the Indigent

Among other important actions of the House were the following:

Physicians were urged to provide medical care for anyone unable to pay for it and county and state medical organizations were urged to implement this principle.

Significant alterations, emphasizing educational aspects of intern training, were adopted for approval of hospitals for internships.

Creation of a federal department of health with cabinet status was again recommended. But the House decided there was no need for an American Medical Association health commission comparable to the President's Health Commission since the various councils and commissions already established are now engaged in doing the job.

For Tax Relief

American Medical Association efforts were endorsed to achieve tax relief for physicians by making expenses of postgraduate education deductible for federal income tax purposes; by allowing physicians to set aside retirement funds from current income without paying taxes on such funds until the benefits are received and by other measures.

A committee was instructed to consult immediately with the American Osteopathic Association concerning use of physicians as instructors in osteopathic schools.

The House also opposed use of prisoners for scientific experiments as a means of gaining clemency. And it recommended withdrawal of the United States from the ILO (International Labor Organization) of the United Nations on the basis that ILO is socialistic and its action could supersede the United States Constitution.

Contributed $500,000

The House contributed $500,000 to the American Medical Education Foundation for support of medical schools. It urged that the meager existing supply of gamma globulin be conserved for civilian use.

It made a large number of changes in form in the Constitution and By-Laws of the American Medical Association in accordance with a directive of 1952 and in the interest of streamlining and modernizing the document and it asked all of the states to explore the precise role of government in the provision of medical service in their states.

Dr. John Mastin Travis of Jacksonville, Texas, was named General Practitioner of the Year.

(Continued on Page 163)

THE MINNEAPOLIS DIABETES DETECTION CAMPAIGN—1952

The most successful of three Diabetes Detection Campaigns was experienced in Minneapolis during the November, 1952, drive.

It was felt that the two previous years had brought outstanding success to this endeavor, participated in by the Twin Cities Diabetes Association, Hennepin County Medical Society, Twin City Retail Druggists Association, and the Minneapolis Health Department. But 1952 exceeded all expectations for response by the public. The 1952 campaign is also noteworthy as the the first year the Dreypak strip method was used in testing.

Total specimens in the three consecutive years and results of testing were:

Year	*Total Specimens Submitted*	*No. Screening Positives*
1950	24,354	534
1951	14,015	258
1952	32,063	657

Each year careful planning by the participating agencies has started months in advance of the November Detection Week. Organization for operation, including collection of specimens, laboratory testing, and reporting to patient and physician; organization for publicity via press, radio, and television, posters, and leaflets; organization for tabulating and evaluating test results and necessary follow-up were all revealed each year again and again to bring about smoothest operation.

Very important to the success of the campaigns was the splendid co-operation of the local press and other media of communication.

In the first two years when liquid urine specimens were accepted, some daily laboratory procedures had to be suspended in the Health Department laboratory where all testing was done during Detection Week. Also, additional technical help had to be sought outside the laboratory staff. In all other phases, the work was absorbed within the normal resources of the Health Department. In the first campaign, only established collection stations of the Health Department were used for collection of specimens. In the two succeeding years, all drug stores of the city became collecting depots, and assistance in collection from these additional stations to the laboratory was given by the Twin City Retail Druggists Association.

Use of the Dreypak strip test method in 1952 greatly simplified the work in the laboratory. This method, authored by Drs. Norman Drey and William H. Olmsted of St. Louis, Missouri, was found on preliminary testing and during the campaign to be as satisfactory as the former methods. Minneapolis served as a pilot study in use of this method for the American Diabetes Association. Through its use, the time-consuming handling of liquid specimens in their original containers of assorted shapes and sizes, their numbering serially with matching number on test tube, to say nothing of disposition of urine and containers after the test had been completed, were all eliminated. In the first two years, the need for processing the liquid specimens as quickly as possible required long hours of work, even into the early morning hours. This was not necessary with the Dreypak as the specimens do not deteriorate rapidly. Aside from the necessary opening of envelopes in which the strips were submitted and serially numbering the strips, the actual laboratory procedure on each strip was only a matter of seconds. At the peak of the load, one technician comfortably processed 7,000 strips in the normal work day.

The participating agencies in Minneapolis are very happy with the results of the 1952 Diabetes Detection Campaign in which the Dreypak method played an important part.

Details of the method and results of follow-up are being prepared for release through the American Diabetes Association. From experience in Minneapolis, it would seem that the Dreypak strip method is well suited for mass testing of urine specimens for the detection of sugar.

AMA CLINICAL SESSION

(Continued from Page 162)

Dr. Travis has practiced medicine for forty-five years in Texas and was called by Dr. Dwight H. Murray, Chairman of the Board of Trustees, who presented him, "a man who exemplifies the best in our system of free enterprise."

Future Meeting Places Named

Plans outlined by the Council on Scientific Assembly for future meetings were approved. They included the New York annual session scheduled for June 2-5, 1953, the clinical session at St. Louis in December, 1953, and the annual session in San Francisco in June, 1954. The clinical session for 1954 will be held in December in Miami.

After a unanimous vote of thanks to the local committee on arrangements, to the Denver Medical Society, the Colorado State Medical Association and their Auxiliaries for the entertainment of the delegates and their wives, the House of Delegates adjourned on Thursday, December 4, 1952.

HOSPITAL ACCREDITATION GROUP ISSUES PROGRESS REPORT

The Joint Commission on Accreditation of Hospitals, charged with the job of carrying on the hospital standardization program conducted by the American College of Surgeons since 1919, has recently issued its first bulletin, containing information on the group's problems and progress since September 1, 1952, when it opened its office in Chicago.

The joint commission has five member organizations and each has a certain number of votes on the commission: The American College of Physicians, three votes; the American College of Surgeons, three votes; the American Hospital Association, seven votes; the American Medical Association, six votes; and the Canadian Medical Association, one vote.

Dr. Edwin L. Crosby, director of the joint commission, states in the first bulletin that one of the first actions taken by the Board of Commissioners of the Joint Commission was the adoption of the program of the American College of Surgeons. He states that a "Grandfather's Clause" was also established which provides that "the Joint Commission will accredit all hospitals for the year 1953 which, at present, have full approval of the American College of Surgeons."

The commission also promises that "accreditation will be continued until an inspection of the hospital under the new Joint Commission program has been made."

Present Standards Retained

The second part of the Grandfather's Clause states that for the present the standards as well as the point rating system developed by the American College of Surgeons will be used as a basis for approval of hospitals. However, Dr. Crosby reports, "as the Joint Commission's program progresses, forms and procedures may be changed. In fact, the JC's Board of Commissioners intends to review the standards critically and, where needed, to make helpful changes."

The Commission bulletin emphasizes that the basic principle of good patient care in hospitals—which has been the criterion for approval during the years the program was under the sponsorship of the American College of Surgeons—will remain intact.

Surveys Outlined

The Joint Commission will assume all responsibility for the accreditation of hospitals on or before January 1, 1953. Actual surveys of hospitals will be conducted as follows:

> "Inspections of hospitals will be conducted by surveyors employed by the member associations of the Joint Commission. At this writing, three of the five associations will have surveyors available for field work by the first of the year. These three groups are the American College of Surgeons, the American Medical Association and the American Hospital Association."

The bulletin emphasizes this fact:

> "Although the survey will be made by representatives of these associations, the actual findings will be submitted to the Joint Commission for evaluation and subsequent accreditation or non-accreditation. In other words, all action on accreditation will be taken only by the Board of Commissioners of the Joint Commission . . . regardless of which particular member association does the inspection of an institution—all decisions on accreditation will be made only by the Joint Commission."

Significance Cited

Dr. Crosby noted awareness of the tremendous significance of this new undertaking. He quoted Dr. Gunnar Gundersen, the Commission's chairman, who said:

> ". . . It is a voluntary movement representing the best thinking and the best inspiration of five of the most powerful groups in the world dealing with health. . . . We recognize what this will mean to the care of

the sick and injured of two friendly nations, Canada and the United States.

"If our duties are discharged well, the benefits to mankind through our profession, through our hospitals, and for our civilization are unreckonable."

By-Laws State Purposes

The purposes of the Joint Commission on Accreditation of Hospitals are stated emphatically in the Commission's thorough set of By-Laws. These purposes are:

> "(a) To conduct an inspection and accreditation program which will encourage physicians and hospitals of the United States and Canada voluntarily:
>

EDITOR HITS "FEDERAL THOUGHT CONTROL"

"Our federal government today employs two methods in the attempt to control the press." An editor of a Southern newspaper made that statement recently when speaking before a meeting of the Florida Medical association.

Virgil M. Newton, Jr., managing editor of the *Tampa Morning Tribune,* spoke on "Federal Thought Control, a Challenge to American Liberties and Freedom," and named the two methods for controlling the press as:

1. Direct and outright censorship. Mr. Newton stated that the best example of this is the censorship of income taxes.
2. Propaganda, which is nothing more and nothing less than attempted thought control. Mr. Newton said, "And it is in this field that our government has waged its campaign for socialized medicine."

He went on to point out that today, according to the Congressional Record, "the federal government is spending $100,000,000 a year for its press releases, prepared by 50,000 government press agents, and $200,000,000 a year for the printing of these releases. That is a total of $300,000,000 a year for federal propaganda."

Explains Methods

Describing how the system worked in the socialized medicine issue, Mr. Newton stated:

> "In 1945, President Truman sent a message to Congress calling for a national health insurance program which was nothing more than socialized medicine. Shortly afterwards, the Surgeon General of the United States Public Health Service sent a letter of instructions to all employes of that government agency. One paragraph of that letter read as follows: 'Every officer of the Public Health Service will wish to familiarize himself with the President's message and will be guided by its provisions when making any public statement likely to be interpreted as representing the official views of the Public Health Service'."

Another official of the Public Health Service, quizzed by a House committee as to why the propaganda issued by his agency supported socialized medicine, replied:

> "We would naturally give emphasis to that, because that is why we are in the government. Otherwise, we should get out of the government."

Commented Mr. Newton:

> "This is a strange concept coming from a public servant of a so-called Democracy . . . implied that if you do not favor socialized medicine, then you have no business in the government. He further implied that it was perfectly all right for a government official to spend taxpayers' funds in pushing our republic down the road to socialism, even though Congress at no time approved any policy favoring socialized medicine or had appropriated funds for such propaganda."

Agencies Issue Material

Mr. Newton reported further that over the years, hundreds and hundreds of pamphlets, booklets and press releases were issued by the Social Security Board, the Public Health Service, the Children's Bureau, the Office of Education, the U. S. Employment Service and the Department of Agriculture, all of which materially supported national health insurance. He cited one pamphlet which said, "You can write a letter to the Readers' Column of your local newspaper, tell your editor why the readers of the paper should back the national health insurance."

Workshops Noted

Among other methods used to foster socialized medicine, Mr. Newton told Florida doctors that the propaganda campaign centered around the "Health Work Shops" which were held in Washington and in other parts of the country. These workshops were conducted by a dozen or more federal security officials who would meet with many carefully selected persons and thoroughly indoctrinate them with socialized medicine views. They would then urge them to conduct smaller local meetings and to spread the word "in such a fashion that a wave of pro-socialized medicine public opinion, even though it be false, would be generated and would sweep across the country and engulf Congress."

Fortunately, however, the opposition to government-controlled medicine grew ever faster, and mounted to sufficient force to let Congress know that Americans wanted no part of it. It is hoped that such propaganda releases from government agencies will be put to a stop now that an administration is in power which is known to oppose government interference.

COMMUNIST LOGIC FALLS SHORT

An interesting observation was seen lately in an advertisement from a manufacturer of machine tools, textiles and machinery. The ad was headed with a quote from the writings of Karl Marx, father of Communist teachings: "From each according to his ability; to each according to his needs." The ad then proceeds to tear apart this basic Communist tennet:

> "A noble sounding philosophy, isn't it?
> "So you take half the bees' hard-earned honey, and give it to the wasps who have spent the summer having an easy time.
> "So half the bees starve to death but the wasps learn to like free honey (there is a special type of wasp that does!) and are now so well fed that they multiply in strength and numbers."

Concluding, the advertisement says:

> "Now they've had a taste of soaking the rich, of 'sharing the wealth'—so they refuse to do any work, and demand *all* the bees' harvest. The now-outnumbered bees try to refuse but the wasps seize the honey, eat it all, and let the bees, who gathered it, starve.
> "So pretty soon you have no industrious bees, and the place is swarming with wasteful, useless wasps.
> "Tough on the bees. And on the world.
> "But such a sweet philosophy!"

LABORATORY AIDS

(Continued from Page 156)

and a 10 per cent (not 0.1 normal) solution of sodium hydroxide to alkalinize the serum and bring out the dye. It is better to use a source of artificial light, such as a fluorescent tube, so that the intensity of illumination is uniform and not variable, as is natural light.

In view of the ease of performance of this test, its freedom from complicating reactions and the valuable information it may provide relative to the state of the liver in nonjaundiced patients, it is surprising that the technique does not enjoy more widespread application.

* * *

This is the second of a series of editorial reports published under the auspices of the Minnesota Society of Clinical Pathologists. As stated in the preceding issue of MINNESOTA MEDICINE, the purpose of these reports is to bring to mind aids to the practice of medicine that may be expected from the wider and more correlated application of laboratory science. Again it should be emphasized that the pathologist is a consultant physician whose specialized knowledge covers a large fraction of medical practice. If this knowledge can be applied to further the welfare of the patient, the pathologist is glad to supply it when he is sought out by the practicing physician. The Society welcomes such consultation and its members are glad for a chance to help resolve any problems that may face the medical practitioner.

In most cases, reprints of these reports will be available from either the author of the individual report or the chairman of the editorial committee of the Society. The members of the editorial committee, Dr. Arthur H. Wells of Duluth and Drs. Arthur H. Sanford and George G. Stilwell of Rochester, welcome any suggestions regarding these presentations.

George G. Stilwell, M.D.,
Chairman, Editorial Committee

"A DISEASE WHICH HAS NO FRONTIERS"

A recent British writer designates tuberculosis as "a disease which has no frontiers." Quarantine cannot be used against it as is possible in foci of plague, cholera or yellow fever. Segregation in sanatoria is our best substitute. But even this has its drawbacks. First, there are not enough beds; second, discharge against advice is still current, releasing infectious cases again into circulation.—KENDALL EMERSON, M.D., *Connecticut State Medical Journal*, May, 1952.

PANCREATITIS COMPLICATING COMMON DUCT SURGERY

VIRGIL J. P. LUNDQUIST, M.D.

Minneapolis, Minnesota

In 1899, Reginald Fitz,[6] writing of acute pancreatitis, stated, "at first sight, the etiological importance of gallstones seems immediate" and "these cases (of pancreatitis) would suggest that these affections were more important from the associated inflammation of the mucous membrane with its opportunity of extension into the pancreatic duct than from the actual or possible perforation of the biliary canal." There are many other interesting historical milestones in the development of our present thoughts concerning pancreatitis. In 1856 Claude Bernard[12] first produced pancreatitis by injecting bile and sweet oil into the pancreatic duct of a dog and caused death in eighteen hours from acute hemorrhagic pancreatitis. Lancereaux[12] in 1899 was the first to suggest that regurgitation of bile into the pancreatic duct might be the cause of pancreatitis in humans. Opie in his classical description in 1901 presented the autopsy evidence of a case of acute hemorrhagic pancreatitis with a stone lodged in the ampulla of Vater.[15] Archibald in 1919 caused pancreatitis in animals by forcing ox bile, human bile and bile salts into the gall bladder under high enough pressure to cause sphincter spasm of the Sphincter of Oddi.[2] This caused the material to be forced back into the pancreatic duct and lead to the development of pancreatitis. He advocated the term pancreatic necrosis since the essential lesion was one of necrosis.

Cameron and Noble,[3] in 1924, using fresh specimens, were able to demonstrate a communication, or common-channel, between the common bile duct and the main pancreatic duct in 74 per cent of their cases. Wangensteen, Leven and Manson,[18] working with cats in 1931, ligated the ampulla and injected air into the gall bladder. This caused a contraction of the gall bladder and a reflux of material into the pancreatic ductal system and a resultant pancreatitis. They concluded that there was a combination of factors working together to cause pancreatic necrosis. Howard[9] has made the statement that there is no definite etiological agent for pancreatitis which is common to all of the cases. C. W. Howell, working at the Minneapolis Veterans Hospital, demonstrated a direct relationship between an elevated serum amylase and filling of the pancreatic duct by cholangiography. In postoperative patients with choledochostomies and T-tubes, he demonstrated that filling of the pancreatic duct was associated with an elevated serum amylase in over 80 per cent of the cases.[12]

From all of these reports we arrive at the conclusion that the common-channel is one of the important factors in the development of pancreatitis. The frequent association between disease of the biliary tract and pancreatitis is one of common knowledge. This association occurs in as high as 70 per cent of the cases of pancreatitis.

It is now generally accepted that the pathological process in pancreatitis is due to the escape of pancreatic enzymes into the gland substance, into the surrounding tissue or into the blood stream. How this escape occurs or how it is initiated is not entirely clear. There is either, (1) an obstructing mechanism within the ducts leading to an escape of inactivated trypsinogen into the tissues where it is activated leading to further digestion, necrosis, and hemorrhage; or (2) there is a reflux of duodenal contents or bile which activates the trypsinogen and leads to trypsin and its subsequent digestive action on the duct, surrounding tissue, and vessels; or (3) there is a traumatic release of the enzymes into the surrounding tissues. It has been demonstrated that there must be a venous absorption of enzymes into the blood stream and that probably a good share of the toxemia associated with pancreatitis is due to the hepatoxic effects of the high amylase content in the portal venous system.[11]

Since the common-channel is important for the development of pancreatitis and since this anatomical arrangement is present in a high number of individuals, it is gratifying that more postoperative cases are not encountered. The many times that the common bile duct is explored for stones by probing and instrumentation would lead one to expect that trauma in the region of the common-channel would precipitate pancreatitis with a much higher frequency.

Pancreatitis is not a frequent complication of biliary tract surgery. Von Schmieden and Segening[19] reviewing 2,137 cases of pancreatitis in which there were 1,278 cases of pancreatic necrosis, found only thirty-eight cases of pancreatitis following biliary tract surgery. In these there were only nine following supraduodenal choledochotomy. Colp and Ginsburg,[5] reviewing 130 autopsies in cases of surgical diseases of the biliary tract, found six cases where pancreatitis

---

Inaugural thesis presented before the Minneapolis Surgical Society, October 1, 1952.

was the cause of death for a percentage of 4.5 per cent. Although the frequency is not great, as will be noted from the cases presented, the prognosis is most unfavorable. It appears that the anatomical arrangement is of some importance for the development of pancreatitis. Two requisites have been advanced for regurgitation.[10] The common-channel must be present or anatomically possible and long enough (at least 5 mm.) to give obstruction to the orifice without obstruction to the ducts. The pressures must be such that the direction of flow is proper. This latter requisite of proper pressures is dependent on whether the main pancreatic duct communicates with the accessory duct or not and whether the duct is patent. Since the duct of Santorini has no sphincter at its orifice in the duodenum, the greater pressure in the duct of Wirsung as compared to the pressure in the common bile duct can be nullified if the duct of Wirsung and Santorini communicate with one another. It has been found that 46 per cent of cases have communications between the ducts of Wirsung and Santorini. This of course gives an avenue of escape to the pancreatic secretion if the main pathway is blocked at the ampulla of Vater.

Various reasons for exploring the common duct at the time of operation on the biliary tract have been promoted.[1] Whether these indications are preoperative such as jaundice, chills, fever, frequent colic, severe nausea, or others; or whether they are operative such as small stones or sand, palpable stones in the duct, contracted gallbladder, or abnormal appearance of the bile, nevertheless numerous ducts are constantly being explored. It is usually thought judicious that drainage of the common duct be done following exploration. This is often accomplished by means of a T-tube. Some have advocated that one limb of the "T" be passed through the sphincter into the duodenum if there be any evidence of stenosis present.[14,17] The diltatation of the sphincter by dilators is also advanced as one of the principles to follow. It has been recommended that this dilatation be done rather vigorously.[13]

Cholangiography done at the time of operation has also been advocated as an aid to determine the presence or absence of disease of the duct. Zierold, as an advocate of this procedure, has not encountered pancreatitis as a complication in several hundred cases. Following this technique, the cholangiogram is most often done as a substitute measure for probing and instrumentation of the duct.[20]

As will be noted from the cases presented, it appears that leaving a tube extending into the duodenum creates a definite hazard and may precipitate an unfavorable outcome. It may also be concluded that cholangiography done at the time of the operation, especially when employed in addition to the usual exploratory procedures on the common bile duct and without control of pressure is not entirely an innocuous procedure. The surgical principle of the gentle handling of tissues, always a virtuous guide, applies as well to the dilatation of the sphincter of Oddi. Pancreatitis does occur following operation on the common duct and has a very poor prognosis.

A review of the literature on this subject reveals cases very similar to those herein presented. Allen[1] reports a patient who developed acute hemorrhagic pancreatitis and died within three weeks following cholecystectomy and common bile duct exploration at which time the sphincter was dilated to 8 mm. Smith[16] described acute pancreatic necrosis occurring in a patient following cholecystectomy and choledochostomy and terminating fatally on the sixteenth postoperative day. This patient had a long-armed T-tube left in with the tube going through the sphincter into the duodenum. The duct of Santorini did not communicate with the duct of Wirsung. Gargas[7] reported a case of acute hemorrhagic pancreatitis with a fatal outcome on the twenty-eighth postoperative day following choledochotomy. Shock was one of the outstanding symptoms in this case. Glenn and Hays[8] reported a case of pancreatitis following choledochostomy which at autopsy showed a large calculus impacted in the ampulla with an anatomical common-channel. Coffey,[4] reviewing 135 cases of pancreatitis with unusual features, encountered two fatal cases of acute hemorrhagic pancreatitis following choledochostomy. One of these had a long-limbed T-tube going through into the duodenum. Three patients had non-fatal pancreatitis resulting from cholangiography at the time of operation using 35 per cent diodrast. In two of these cases the pancreatic duct was visualized on the cholangiogram.

The following cases are presented to demonstrate the development of pancreatitis complicating surgery of the common bile duct:

Case 1.—C. M., a woman aged thirty, was admitted to the hospital November 9, 1950. Right upper quadrant pain, food dyscrasia, belching, and jaundice had been present for two weeks. Pruritus and acholic stools had been present one week. Examination showed icterus, and tenderness in the right upper quadrant. There was a poorly functioning gallbladder on cholecystogram. At operation two stones were removed from the common bile duct; cholecystectomy and choledochostomy were done. The sphincter was dilated to 7 mm. and a long-limbed T-tube left with one limb through the sphincter into the duodenum.

Thirty-eight hours postoperatively the patient developed profound vasomotor collapse. The shock responded to treatment for a time but the jaundice increased, the hypotension persisted, and the patient expired seventy-two hours postoperatively.

At autopsy, massive acute hemorrhagic pancreatitis with profuse fat necrosis in the peritoneal and pleural cavities was encountered. The long limb of the T-tube obstructed the main pancreatic duct of Wirsung at the common channel and the accessory (Santorini) duct did not communicate with the main pancreatic duct.

Case 2.—W. M., a man, aged sixty-four, was admitted to the hospital on May 16, 1951. He gave a history of noting melena intermittently for two years. The examination was noncontributory except for a suspicious small bowel lesion on x-ray examination. The cholecystogram was negative.

Exploratory laparotomy was done and stones were found in the gallbladder and also in the common bile duct when it was explored. Cholecystectomy was done and cholangiography carried out at the time of the operation. The sphincter was dilated to 7 mm. and a short limbed T-tube left in the common duct.

Postoperatively the patient did poorly and the course was progressively downhill. Forty hours postoperatively there was profound shock. The serum amylase was 242. There was pronounced drainage of sloughed necrotic pancreas and the patient went on to expire on the forty-eighth postoperative day.

Case 3.—O. P. was a seventy-year-old male admitted to the hospital on July 16, 1951, with a complaint of intermittent epigastric pain and food dyscrasia of one year's duration. There had been occasional jaundice and acholic stools with these episodes.

Examination revealed icterus of the skin and sclerae. The urine showed positive bile and the serum amylase was normal.

Cholecystectomy was done and common duct exploration carried out. A stone was removed from the lower end of the common duct. The sphincter was dilated to 7 mm. A short limbed T-tube was left in the common duct.

On the sixth postoperative day the patient developed severe substernal pain and hypotension. A diagnosis of coronary occlusion was made. The patient gradually lost ground and expired on the nineteenth postoperative day.

Autopsy showed pancreatic necrosis in the head of the pancreas. The heart was normal.

Case 4.—G. S., a man aged fifty-eight, was admitted to the hospital on July 25, 1951. The history was that of epigastric distress for two years. There had been relief obtained with soda and vomiting. For one week before admission he had had severe abdominal pain of an acute nature and periods of colic.

Examination showed an acutely ill man with an enlarged liver and a tender mass below the liver thought to be the gallbladder.

After two weeks of conservative treatment without much improvement operation was undertaken. A subacute cholecystitis was found and the gallbladder was removed. Common duct exploration was carried out, the sphincter dilated to 5 mm., and cholangiography done at the time of the operation. T-tube drainage was established using a short limbed tube.

The patient did not do well postoperatively. He failed to establish peristalsis and had several periods of hypotension responding to conservative treatment temporarily. Of the seventh postoperative day a mass developed in the operative area and drainage of an acute pancreatic necrosis was instituted. He expired on the seventeenth postoperative day. At autopsy marked pancreatic necrosis was found.

Case 5.—B. H., a man aged fifty-seven, was admitted to the hospital on June 27, 1952. There was a thirty-four-year history of intermittent, nausea, epigastric pain, and vomiting. Fourteen years previous an operation had been performed for suspected perforation of a duodenal ulcer and an acute pancreatitis had been encountered. He had an acute exacerbation of symptoms the day before admission.

Examination showed epigastric tenderness and evidence of rebound tenderness. The white blood count was 19,850 and the serum amylase 3036 units.

After one month of conservative management with complete subsidence of acute symptoms, cholecystectomy was done. Common duct exploration was carried out. The sphincter was dilated to 5 mm. and a short limbed T-tube left for drainage. Cholangiography was done after the exploration at the time of operation.

The patient had a febrile postoperative course, jaundice became marked, there was profuse bile drainage, and leukocytosis of 23,350 developed. A bile abscess followed and was drained. The drainage was profuse. A mass in the operative area was surgically drained and pancreatic necrosis encountered. The patient became a feeding problem, feeding jejunostomy was established but he gradually lost ground and expired on October 19, 1952.

Conclusions

1. Pancreatic necrosis does occur following surgery of the common bile duct.

2. The prognosis after its development is very unfavorable.

3. Trauma to the sphincter by rough handling and instrumentation may precipitate reflux and the development of pancreatitis.

4. Leaving of the tube through the sphincter into the duodenum may block the outlet of the pancreatic duct and promote development of pancreatic necrosis.

5. Cholangiography done at the time of operation without adequate control of pressure may have an adverse effect and be a factor in the development of pancreatic necrosis.

CARCINOMA OF CARDIAC END OF STOMACH AND ESOPHAGUS

CHARLES B. PUESTOW, M.D.
Chicago, Illinois

Carcinoma of the cardiac end of the stomach and of the esophagus is a more common disease than is generally recognized by the medical profession. As the patients admitted to the Veterans Administration Hospital, Hines, Illinois, are largely residents of the surrounding area, the statistics from this hospital should give a fairly accurate indication of the incidence of this disease among adult males of the Middlewest. Patients admitted to this hospital during the past five years included those with carcinoma of the lung, colon, stomach and esophagus in the following number and approximate ratio:

1946-1951

	No. of Cases	Ratio
Lung	606	4
Colon	495	3
Stomach	288	2
Esophagus	135	1

It is interesting to note that for every two patients admitted with carcinoma of the stomach, one patient is admitted with carcinoma of the esophagus. Of the patients with carcinoma of the stomach, a large number have had the disease located in the proximal portion of this organ.

Carcinoma of the Esophagus

Carcinoma of the esophagus has been a neglected disease because until recent years the physician had little to offer the patient. As a result, the recognition of this disease and the methods of study have been disregarded. Almost invariably tumors of the esophagus manifest themselves months before they are diagnosed and a longer time elapses before the patient is referred to a surgeon competent to administer adequate therapy.

A careful analysis of patients with carcinoma of the esophagus has shown three early symptoms. The first of these is anorexia. The loss of appetite of patients in middle or later life is the earliest symptom of carcinoma of the esophagus and of the proximal stomach. This symptom should suggest to the physician the possibility of such a lesion. A relatively short time later the patient complains of a vague substernal discomfort often associated or soon followed by some difficulty or distress in swallowing solid food. These symptoms suggest a lesion of the esophagus, and demand immediate study of this structure.

Late symptoms of carcinoma of the esophagus consist of difficulty in swallowing soft foods or liquids, progressive weight loss and occasionally hematemesis. If these symptoms develop, they are usually an indication of an advancement of the disease to a stage where complete cure is impossible because of direct or metastatic spread.

Methods of Diagnosis.—In the very early stages of carcinoma of the esophagus, the lesion often can be recognized only by esophagoscopy. When it is very small, roentgenologic studies may not reveal this disease. If a suspicious lesion is seen through the esophagoscope a biopsy is indicated. Many endoscopists fear biopsy because of the danger of perforation of the esophagus and the development of mediastinitis. In the past this was a serious complication. At present its dangers are greatly minimized by the use of antibiotics and the surgical approach to this complication.

Roentgenologic studies often will reveal carcinoma of the esophagus even at an early stage. In the past, roentgenologists neglected the esophagus in gastrointestinal studies. Their interest and study of this organ in recent years has enabled them to diagnose many early lesions. The entire medical profession must realize that the gastrointestinal tract does not begin in the mid portion of the stomach, if early diagnosis of lesions of the esophagus and proximal stomach are to be made.

It is interesting to note that although anatomy of the stomach is an old science, it has only been recently recognized that all blood supply to this organ, except that supplied through the right gastric and right gastroepiploic arteries, can be interrupted and the organ will remain entirely viable and anastomotic procedures at its fundus will heal in a normal manner. Only recently was it realized that the stomach could be transplanted into the chest or even through the chest and into the neck to replace the entire esophagus with easy and with little physiologic disturbance.

Principles of Surgical Approach.—The entire stomach and thoracic esophagus can be dealt with surgically by a resection of the seventh left rib and an incision through the diaphragm. If the esophagus above the arch of the aorta is to be utilized, access to it is facilitated by division of the posterior end of the left sixth and sometimes fifth rib. Some surgeons prefer to approach the esophagus through the right chest. This necessitates mobilization of the stomach through an additional abdominal incision. We prefer the left thoracic approach because it involves less surgical time and trauma. We have always been able to mobilize the esophagus behind the arch of the aorta through a left thoracic incision in operable lesions. If the carcinoma involves the cervical esophagus, we prefer to first approach it

---

Dr. Puestow is Clinical Professor of Surgery, University of Illinois College of Medicine, and Chief, Surgical Service, Veterans Hospital, Hines, Illinois.

Published with the permission of the Chief Medical Director, Department of Medicine and Surgery, Veterans Administration, who assumes no responsibility for the opinions expressed or the conclusions drawn by the author.

through a neck incision to determine its operability. If the lesion can be resected, the left thorax is then entered, the stomach and esophagus mobilized and the stomach brought up through the chest anterior to the aorta and into the neck incision where it can be anastomosed to the cervical esophagus above the lesion. Lesions of the lower esophagus which can be satisfactorily removed and the stomach anastomosed to the esophagus below the arch of the aorta are approached by resection of the left eighth rib.

High Gastric Lesions

Malignant lesions of the proximal stomach can be readily approached by resection of the left eighth rib and an incision through the left diaphragm. This approach gives direct access to the stomach and surrounding organs which may be invaded by tumor, including the left lobe of the liver, spleen, pancreas, left adrenal gland and the portion of the diaphragm surrounding the esophagus. It permits an extensive glandular resection, especially in the region of the celiac axis. It also permits a wide omental resection. It is our belief that the incidence of cure or prolonged palliation is more dependent upon the extent of resection of gland bearing tissue than upon the amount of uninvolved stomach removed. We prefer to save some normal stomach if possible because we believe this leads to greater subsequent physiologic comfort.

Postoperative Care

The postoperative care of patients undergoing gastroesophageal resection is as important as the surgical technique employed. This care should be the joint responsibility of the surgeon, anesthesiologist, and well trained recovery room personnel. The following points are emphasized in the postoperative management of these patients.

A. Stir-up Regime.—Patients are frequently moved from side to side and urged to move around in bed. They are ambulated early.

B. Tracheo-bronchial Aspiration.—The patient is constantly observed for evidences of tracheo-bronchial occlusion. When this occurs, immediate aspiration by tracheal catheter or bronchoscope is instituted. We do not believe routine tracheotomy is advisable or necessary for the removal of bronchial secretions.

C. Suction.—A double lumen tube is placed at the time of operation with the suction portion in the stomach and the feeding limb extending into the small bowel. Constant suction is maintained to avoid distention which may place traction on the suture line and also interfere with the cardio-respiratory system.

D. Sedation.—The use of opiates is discouraged. Thoracic pain is controlled by intercostal block. This permits the patient to breathe deeply without pain and minimizes pulmonary complications.

E. Oxygen Therapy.—Oxygen is administered only when there is evidence of oxygen want. It is administered by nasal catheter or oxygen mask. We are opposed to the use of oxygen tents because they interfere with other postoperative measures.

F. Nutritional Balance.—An effort is made to replace blood, volume for volume, by careful determination of the amount lost at operation. Additional blood is not given unless there is evidence of anemia. Other fluids and nutritional elements are given as indicated, and caution is taken not to overload the circulation.

G. Antibiotics.—The use of antibiotics is important but does not replace other factors in good postoperative care.

A well organized recovery room with trained personnel is a great aid to the recovery of patients undergoing transthoracic gastroesophageal surgery.

Results

Mortality.—The mortality of gastroesophageal surgery has been noticeably diminished and should not be higher than in other types of major surgery performed upon similar types of patients. The most important single factor responsible for postoperative complications is the poor nutritional state of these patients when they are presented to the surgeon, and the difficulty of improving their nutritional state before operation.

Cure.—We believe that carcinoma of the esophagus can be cured in a higher percentage of cases than carcinoma of the stomach. This is probably not true at present because of the advanced stage of the disease at the time of operation. Our patients have had symptoms for periods ranging from three months to over a year and usually have lost from twenty-five to seventy-five pounds in weight. As this disease tends to produce symptoms in its early stages, its early recognition and treatment should improve surgical results.

Palliation.—Even though the disease has spread to adjacent structures where it cannot be entirely irradicated or has metastasized to other organs, removal of the local lesion and re-establishment of the continuity of the esophagus and stomach can give patients many months of comfort during which time they are able to ingest food and are relieved of the distressing symptoms of starvation.

The meeting adjourned.

Albert T. Hays, M.D., *Recorder*

Minnesota Academy of Medicine

Meeting of October 8, 1952

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town & Country Club on Wednesday evening, October 8, 1952. Dinner was served at 7 p.m. and the meeting was called to order at 8:15 p.m. by the President, Dr. Owen H. Wangensteen.

There were forty-two members and six guests present.

Minutes of the May meeting were read and approved.

Dr. Lowry, Chairman of the Program Committee, asked the members to send in titles of papers or cases they would like to present during the coming year.

Dr. John E. Hynes read the following Memorial to Dr. Charles D. Freeman, and a motion was carried that it be spread on the records of the Academy and a copy sent to the family of Dr. Freeman.

CHARLES D. FREEMAN, 1879 - 1952

Charles D. Freeman was born in St. Paul on January 20, 1879, son of George and Mrs. Freeman. He was graduated from Central High School, and attended the University of Minnesota two years in the College of Science, Literature and Arts, before deciding upon a career in Medicine. He matriculated in the University of Minnesota Medical School in 1900, and was graduated in 1904. After a year as intern in Luther Hospital, he spent two years in postgraduate study in Vienna, Berlin, Paris and London, specializing in Dermatology, and returned to St. Paul where he practiced until his retirement three years ago.

He was a member of the American Medical Association, Minnesota State Medical Association, Ramsey County Medical Society, a Past President of the Minnesota Academy of Medicine, and a member of the American Dermatological Society. He was on the staffs of Ancker, St. Joseph's, and St. Luke's Hospitals, and a member of the University of Minnesota Medical School teaching staff.

As it must come to all things mortal, death came to him on April 18, 1952, at the age of seventy-three years. He is survived by his wife, two daughters, Margaret and Helga, and a son, Dr. Charles D. Freeman, Jr., all of St. Paul.

In addition to his other good qualities, his one great characteristic was friendliness. We do not believe he had an enemy in the world.

No better example of love and selfless sustaining devotion could be possible than that of his wife in his last long illness.

Ave, atque vale!

John E. Hynes, M.D.
Harold E. Hullsiek, M.D.

Dr. Eldon B. Berglund of Minneapolis [by invitation] gave a paper on "Surgical Approach to Atelectasis in the Newborn."

SURGICAL APPROACH TO ATELECTASIS IN THE NEWBORN

O. S. WYATT, M.D., T. C. CHISHOLM, M.D., E. BERGLUND, M.D.,
and W. P. EDER, M.D.
Minneapolis, Minnesota

Atelectasis of the newborn accounts for approximately 50 per cent of all deaths in the neo-natal period. The causes of atelectasis in the newborn are still the subject of controversy. One group feels that aspiration of the amniotic fluid during the time of delivery results in failure of the lungs to expand properly. Another group contends that aspiration of the amniotic fluid does not account for the development of the atelectasis. Over recent years attention has been focused on the so-called hyaline membrane, a pink staining homogenous material lining the alveolar ducts which is seen on microscopic section of lungs of newborns dying of the clinical picture of the atelectasis.

The disease occurs most commonly in premature infants but may be seen in full term infants. The diagnosis during life is based primarily on clinical findings. These babies develop respiratory distress in some instances immediately after birth, in other instances not until several hours have elapsed. They become cyanotic when removed from oxygen, but the cyanosis is relieved quickly with oxygen. They have moderate to marked intracostal retractions often accompanied by short, whining cries. Clinical and x-ray examinations can quite accurately exclude the presence of such conditions as diaphragmatic hernia, congenital heart disease, spontaneous pneumothorax, and brain damage which may minimize the symptoms of congenital atelectasis.

The treatment in the past has been primarily symptomatic and quite unsatisfactory. About 50 per cent of the infants with the well-developed clinical picture recover spontaneously. Over the past three years we have attempted a surgical procedure on twenty-three newborn infants who appeared to be succumbing to congenital atelectasis. An equal number of infants have been seen and not operated upon. This report concerns primarily the infants who were operated upon. Of the twenty-three infants, eleven have survived, twelve have died. Twelve of the infants were delivered by cesarean section, an incidence which would, to our minds, definitely establish cesarean section as a causative factor in the development of the congenital atelectasis. Of the remaining infants, only four were considered to have been normal deliveries. The others were delivered with such complications as precipitate delivery, abruptio placenta and marginal placenta previa. Our findings in this respect would definitely implicate abnormal deliveries of one kind or another as being contributory in the development of congenital atelectasis, probably because of the increased chances for aspiration of amniotic fluid and the subsequent development of a hyalinc membrane during and following such delivery.

The surgical procedure consists of opening the chest with a short incision through the fourth and fifth interspace on one side. Positive air pressure ranging up to 35 cc. of water is applied through the nose and mouth by a tight-fitting mask. In five instances there was a dramatic expansion of the lungs. These babies survived. In six instances there was no dramatic expansion of the lungs, but these babies also survived. In the remaining patients expansion of the lungs was negligible and the infants did not survive. Many of the infants were moribund at the time of operation.

This experience with congenital atelectasis of the newborn has not led to a completely satisfactory method of treatment. It has helped us to understand the disease process better and has, to our minds, established the importance of the abnormal delivery as one factor in the development of the disease, and it has, in some instances, we believe, helped babies to survive.

Discussions

Dr. W. P. Eder, Minneapolis (by invitation): There is very little I can add to Dr. Berglund's excellent presentation. Perhaps just a word about the rationale of the surgery itself. We had considerable arguing to do to convince the chest surgeons that the procedure had merit. The lungs occupy the entire thorax; therefore, the pressure applied does not expand the lung. It does not help in overcoming the hyaline membrane which Dr. Berglund mentioned. The lung expands with positive pressure. The mediastinum shifts to the side of the thoracotomy and therefore assists the lung on the opposite side to expand. We have been very much interested in this problem. I feel strongly that these eleven infants that survived would definitely not be alive had we not done this procedure.

Dr. Thomas Lowry, Minneapolis: I don't have a great deal to add. I was privileged to watch one of these procedures (one of the ones which did not result in recovery) but it was a most interesting thing. I don't have enough experience with the condition or its treatment to say much about it. I enjoyed Dr. Berglund's presentation and think we will all be watching to see what success is accomplished.

Dr. M. B. Visscher, University of Minnesota: This is a very interesting problem from the physiologic viewpoint and I was very much interested in the report Dr. Berglund and his associates have given. Atelectasis is a very difficult term to define, as these gentlemen know very well, and I am not quite sure that it is fair to call the situation that they have studied a true atelectasis. If their criterion for diagnosis is valid, namely, that on administration of oxygen the cyanosis is relieved, the lung is not atelectatic but is more likely edematous. In simple atelectasis, administration of 100 per cent oxygen has little effect upon the arterial oxygen saturation. In pulmonary edema 100 per cent oxygen has very large effects. I would suggest that a study be made of the state of the heart in these newborns. It is extremely likely that left heart failure will be found. Full expansion of lungs with interstitial edema improves blood oxygenation and indirectly relieves heart failure.

May I also raise the question as to whether all possible non-surgical methods for producing greater lung expansion have been tried.

I think there is a lot of very interesting physiology here and want to congratulate the authors on these studies.

Dr. Harold Flanagan, St. Paul: I enjoyed this paper very much; there has been a great deal of work done in producing this paper. Some weeks ago I saw a newborn infant that I thought was a congentital heart. I gave morphine with almost immediate improvement. The infant had an atelectasis, and the relaxing effect of the morphine on the diaphragm and gastric distention, must have been the cause of the immediate improvement.

Dr. Jerome Hilger, St. Paul: I should like to comment on what Dr. Berglund has said about endoscopic procedure for the relief of this infant problem. For many years we were called by the pediatricians quite frequently to relieve these children through endoscopic aspiration. It became apparent to us that much of our effort was futile and that in the average case retained secretion available to tracheo-bronchial aspiration was not present in any significant quantity and the effort at aspiration in no way eased the child's problem.

We even had the American Cystoscope people make us a fiber catheter with a Coude angle at the tip with the end open. This was less traumatic than a bronchoscope and just as effectively cleared the sub-glottic trachea and bronchi. It could be directed right or left into the major bronchi. Even its insertion disturbed some of these children a very great deal and we had the feeling that the aspiration in some cases caused more disturbance than improvement. This flexible aspiration catehter, however, did permit one to connect oxygen directly into the trachea and insufflation after the aspiration was very helpful in maintaining a good color. This is very difficult to do with a bronchoscope in place without a great deal more trauma.

It must be borne in mind, however, that the same clinical picture that Dr. Berglund presents can be duplicated by an occasional laryngeal problem developed in the prenatal period such as a laryngeal cyst or web. Since this is true, unless first the larynx and upper air passages are viewed directly, an occasional child with such a lesion is going to have a thoracotomy to no purpose.

Since the thoracotomy does nothing in effect but create space for the lung expansion to take place, and since the latter is accomplished by bag breathing, I would like to ask what other work has been done using this same pressure through the airway but using other methods of increasing the thoracic space for expansion. After all, in normal breathing, we increase our thoracic space by lowering the diaphragm and increasing the rib cage size. I assume there is nothing to prevent the rib cage from increasing in these flaccid chest walls. In so far as lowering the diaphragm goes, certainly the biggest disadvantage is the gas-filled stomach below. If this were decompressed with a continuous in-dwelling catheter in the stomach during the bag insufflation, one would feel as much would be accomplished by the bag pressure under these circumstances as through the creation of more space through an open thoracotomy.

Dr. Berglund, in closing: Dr. Hilger asked what work has been done in creating pressure through the mouth and the patient's larynx and how we keep the stomach deflated? We have done that at the time of the procedure. We oftentimes just push our hand on the baby's abdomen. One of the procedures that has been tried is to introduce oxygen into the stomach and let it flow out through a second tube. Ten per cent of the baby's oxygen needs can be maintained by that means. As far as applying pressure to the lungs before operation, we tried that; we had the anesthetist apply pressure in one case for forty minutes; after that time we opened the chest and found the lungs completely atelectatic. We were convinced by that, and also from what I have read in the literature, that application of positive pressure before the chest is opened does not work. We have not done that as a routine procedure since those early experiences. We felt that opening the chest itself enables the operator to see the lung and see how long the pressure needs to be applied.

Dr. S. R. Maxeiner, Minneapolis, read a paper on "Synovioma; Diagnosis, Prognosis and Treatment."

SYNOVIAL SARCOMA

Report of Five Cases

STANLEY R. MAXEINER, M.D., F.A.C.A., F.I.C.S.
and
B. H. MCLAUGHLIN, M.D.
Minneapolis, Minnesota

Synovial sarcoma is a tumor with which surgeons are apparently little acquainted. It is extremely malignant, arising from serous lining of synovial cavities (joint synovial lining and the synovial linings of overlying bursae).

More and more cases are reported in the recent literature, not because of its increased frequency, but because of the awareness of our profession. In 1949, the Mayo Clinic reported only twenty-eight cases with approximately 222 cases reported in the total literature to that date. McCartney of the Department of Pathology of the University of Minnesota, in 1945 reported eight cases, all encountered within the last five years.

Etiology

Sex.—Sex apparently plays no important part.

Age.—The average age of the reported cases is approximately thirty-six years.

Trauma.—Trauma has been considered, but little definite proof has been established as an etiologic feature.

Inflammation.—Inflammation may be an etiologic feature.

Location.—The majority of the tumors are located in or near the knee joint. Other common sites are, the foot, thigh, ankle and hand. The majority of reported cases have been found to involve the extremities.

Symptoms.—The prevailing clinical symptoms are: (a) pain; (b) presence of a mass; (c) joint dysfunction; (d) fluid swelling of the joint. The average duration of symptoms before diagnosis is probably from two to three years.

Diagnosis.—A positive diagnosis is made only by microscopy. These tumors are variable in size, texture, color and consistency. Usually the synovioma is circumscribed by a pseudocapsule. Its consistency may be firm, moderately fibrous, spongy or friable. Pinkish-grey areas of viable tumor are frequently interspersed with yellow areas of necrosis and brown or red portions resulting from old or recent hemorrhages. Occasionally, there are small areas of calcification. There are three basic morphologic patterns:

1. Formation of tissue spaces that form slitlike clefts to well-defined gland-like spaces containing a serous or mucinous fluid. The mucin production may be confined to the gland-like spaces or may appear as small interstitial accumulations among the endothelial components of the tumor cells.

2. Formation of cell tufts, which varies from compact groups of oval or polygonal cells segregated in solid portions of the tumor to papillary projections extending into clefts and gland-like spaces.

3. Reproduction of epithelial-like cells on a stroma of compact elongated cells with small dark nuclei. There may be a supporting prominent argyrophilic recticulum. Extension of the tumor into vascular channels and invasion into adjacent tissue may occur. Mitotic figures are observed fairly frequently. All synovial sarcomas are malignant, but it is the consensus that they are not all equally malignant. The least malignant are those showing a high degree of histiocystic differentiation, characterized by multinucleated giant cells, pigmented cells and fibrous areas. The most highly malignant are probably those composed of densely packed round, oval and reniform cells, with much supporting reticulum and numerous mitotic figures.

(The above description is by Dr. R. Sanford, Pathologist, Asbury Hospital, Minneapolis.)

Treatment.—Treatment is first dependent on an accurate indisputable diagnosis of a malignant synovioma. Radical surgical resection is recommended by some, but is probably grossly inadequate in view of the long time low survival rate. Most writers of experience, advocate radical amputation immediately. The tendency for the lesion to invade is strongly in favor of amputation. Lower quarter resection probably has no advantage over a hip disarticulation.

Prognosis.—The prognosis in synovial sarcoma is poor. The disease spreads by invasion, by lymphatics

---

Dr. Maxeiner is Clinical Professor of Surgery, Department of Surgery, University of Minnesota School of Medicine.

and by the blood stream. Dr. Coventry of the Mayo Clinic at the time that I talked to him, stated that they had no patients alive and well at five years. Three of our five patients reported expired from pulmonary metastases.

Report of Cases

Case 1.—A white woman, forty years of age, consulted us in February of 1950, complaining of a mass on the inner aspect of her right thigh. Her general condition was excellent. Her family and past history, general physical and laboratory examination, together with chest x-rays, were unimportant.

The mass was completely removed, together with a very wide muscular excision and excision of the superficial femoral vein. There was considerable difficulty in obtaining a microscopic diagnosis, several opinions being ventured, and about five days later a consultation of pathologists confirmed the diagnosis of synovioma. An immediate exact frozen section diagnosis seemed impossible. The operation was followed by a series of high voltage x-ray treatment. Although reports in the literature admit little if any effect from x-ray therapy, it is still recommended.

One year later, the patient again returned with a mass in the same location and an exarticulation of the hip was done. Again the pathological report revealed the diagnosis of recurrent malignant synovioma. The patient did extremely well for a number of months at which time she complained of dyspnea and pain in her chest. Roentgenograms revealed extensive pulmonary metastases from which she expired only four months after her second operation.

Case 2.—Mr. T., aged forty, whose family history and previous illnesses are irrelevant, stated that, in 1944, while in the military service he developed pain in his foot. An ankle fusion was done and subsequently a mass appeared on the bottom of his foot. This was excised and a diagnosis of malignant synovioma prompted immediate amputation below the knee. This was done at the United States Veterans Hospital in Minneapolis. To date, the patient is well. Pathological examination of the foot, revealed remaining tumor tissue.

Case 3.—Also reported from the records of the United States Veterans Hospital in Minneapolis, is the case of a man, aged twenty-three, whose history is unrevealing except as related to his present complaint.

He stated that, in 1947, there was swelling with chilling and fever and inability to straighten his arm. Examination revealed a cystic swelling deep to the biceps and about the size of a baseball.

Through an anterior approach, the mass was removed. The tumor was attached to the elbow joint capsule. The pathological report was synovial sarcoma of the left elbow. The patient refused amputation and was given extensive x-ray therapy. One year later, examination revealed multiple pulmonary metastases from which he expired.

Case 4.—From the records of the United States Veterans Hospital in Minneapolis, also is reported the case of a man, aged twenty-nine, whose family and past history were noncontributory. The symptoms were first noted in 1944, while he was in the navy.

In 1951, the patient was seen at the Veterans Hospital with a tumor of the right knee, anterior and lateral to the patella, measuring 2 x 3 inches. The tumor was firm and nodular, but not tender. It was widely excised under general anesthesia. The frozen section was reported as a xanthoma, but the first permanent section revealed a synovioma. An amputation was not done, but the patient was given extensive x-ray therapy. He subsequently developed pulmonary metastases.

Case 5.—This is the case of a man, aged thirty, who stated that sixteen years earlier he was operated on for a tumor of his right elbow. It was operated on again in 1946, for the third time in July, 1947, and again in November, 1947. The tumor produced no symptoms, other than a mass in the region of his elbow, approximately 3 x 3½ inches. The mass was widely excised, together with surrounding and invaded tissues. The microscopic diagnosis was fibrosarcoma of the synovial type. In February of 1948 another recurrence was removed and in April of 1948, the patient was seen by Dr. Willard White who performed a disarticulation of the shoulder. Healing was excellent, and there has been no recurrence to date. This history of repeated operations is extremely unusual.

Summary

Synovial sarcoma, i.e., malignant synovioma, must not be confused with giant cell synovioma or other tumors. Pathological diagnosis is apparently difficult, and one must be careful and be positive of a diagnosis of synovial sarcoma, before amputation, the most widely accepted procedure, is advised. The survival rate is extremely low, but we believe that an immediate diagnosis with radical surgery affords the best opportunity for a cure.

The meeting was adjourned.

Wallace P. Ritchie, M.D., *Secretary*

DRUGS TESTED IN TREATMENT OF TUBERCULOSIS

After a review of available data on the action of isonicotinic acid hydrazide and its isopropyl derivative upon the tubercle bacillus *in vitro,* and upon the course of experimental tuberculosis in animals and clinical tuberculosis in man, it may be stated that their demonstrated action, although highly encouraging, appears in no way to alter the basic principles of the treatment of tuberculosis as presently understood. Much more work will need to be done to ascertain the exact place of these drugs in the treatment of this disease. It is anticipated that further information will accumulate rapidly.—The Executive Committee of the American Trudeau Society (Medical Section of the National Tuberculosis Association), *Tuberculosis Abstracts,* May, 1952.

POSTGRADUATE COURSE—DISEASES OF THE CHEST

The Sixth Annual Postgraduate Course in Diseases of the Chest sponsored by the American College of Chest Physicians, Pennsylvania Chapter and the Laennec Society of Philadelphia, will be presented at the Bellevue-Stratford Hotel, Philadelphia, Pennsylvania, March 23-27, 1953.

This course will emphasize the recent developments in all aspects of the diagnoses and treatment of chest diseases. The course is open to all physicians; however, the number of registrants will be limited.

The tuition fee is $50 and applicants will be accepted in the order in which they are received. This course has been approved for credits by the American Academy of General Practice. Applications should be sent to the Executive Director, American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois.

* * *

CONGRESS OF PHYSICAL MEDICINE AND REHABILITATION

The thirty-first annual scientific and clinical session of the American Congress of Physical Medicine and Rehabilitation will be held August 31, September 1, 2, 3 and 4, 1953, inclusive, at the Palmer House, Chicago, Ill.

Scientific and clinical sessions will be given on the days of August 31 and September 1, 2 and 3. All sessions will be open to members of the medical profession in good standing with the American Medical Association.

In addition to the scientific sessions, annual instruction seminars will be held. These lectures will be open to physicians as well as to therapists, who are registered with the American Registry of Physical Therapists or the American Occupational Therapy Association.

Full information may be obtained by writing to the executive offices, American Congress of Physical Medicine and Rehabilitation, 30 North Michigan Avenue, Chicago 2, Illinois.

KENFIELD MEMORIAL AWARD

Competition for the 1953 Kenfield Memorial Scholarship, awarded annually by the American Hearing Society to a prospective teacher of lipreading to the hard of hearing, opens March 1. Application blanks may be obtained from Miss Rose V. Feilbach, chairman of the Society's Teachers Committee, 1157 North Columbus St., Arlington, Va. Deadline for returning applications, completed, is May 1.

Funds for the scholarship were subscribed in 1937 in memory of Miss Coralie N. Kenfield, San Francisco, Calif., who was nationally known for her advanced methods in teaching lipreading. Winner of the award is entitled to take a teacher training course in lipreading from any normal training teacher, school or university in the United States acceptable to the American Hearing Society's Teachers Committee. The scholarship is to be used within one year from date of award.

An acceptable applicant for the scholarship must be a well-adjusted individual with a pleasing personality, legible lips, a good speech pattern and no unpleasant mannerisms. Graduation from college with a major in education, psychology and/or speech is a requirement. Specifications for a hard-of-hearing contestant include thirty hours of private instruction in lipreading from an approved teacher or sixty hours of lipreading in public school classes under an approved teacher. Rules for competition state that an applicant shall plan to teach lipreading, with or without other types of speech or hearing therapy.

In 1952 the Kenfield Memorial award went to Miss Marion R. Allen, Minneapolis, Minnesota.

MANUAL FOR ARTHRITIS CLINICS

A manual for Arthritis Clinics has just been published jointly by the Arthritis and Rheumatism Foundation and the National Institute of Arthritis and Metabolic Diseases. This sixty-four-page book contains practical information on the administration of a clinic for the rheumatic diseases as well as diagnostic criteria, information on selecting and training a clinical staff.

Copies are 50 cents and may be obtained by writing to any of the thirty-two chapters of the Foundation, or to National Headquarters, 23 W. 45th Street, New York 36, New York.

HEART SPECIALTY TRAINEESHIPS

Fifteen young physicians have recently been given special training awards under the clinical traineeship program of the National Heart Institute. A total of thirty-two physicians are now receiving heart traineeships, studying in twenty-five institutions in twelve states and the District of Columbia.

Four Minnesota doctors studying under this program are Dr. Bertram Levin, Heart Hospital, Minneapolis; Dr. William F. Maloney and Dr. Daniel H. Simmons at the University of Minnesota Hospitals, Minneapolis, and Dr. Leo Wright at the Mayo Foundation, Rochester.

Since the inception of the program four years ago, 149 physicians have been given the opportunity to acquire special skills in diagnosing and treating the heart diseases which afflict about nine million people in the United States. The majority of these doctors have completed their periods of study and are helping to relieve the serious shortage of physicians who understand techniques of interpreting electrocardiograms, carrying out cardiac fluoroscopy and correlating various diagnostic findings. These doctors will apply and develop their new skills to

improve the health or lengthen the lives of the people they treat, whether as staff members of cardiology departments in hospitals, or in carrying on a high level of private practice.

Traineeships carry stipends of $3,000 per year for trainees without dependents and $3,600 for those with dependents. Eligible for such special study are doctors who are citizens, who have completed a general internship, have at least one additional year of experience or training, and are not over forty years of age. Applications for the traineeships may be obtained from the National Heart Institute, Public Health Service, Bethesda 14, Maryland.

NATIONAL COUNCIL ON RURAL HEALTH

One of the ways in which the physicians of the country are making an effort to improve medical care to citizens and their families is by the holding each year of a National Conference on Rural Health. It is recognized that those who live in the country have special problems which require attention.

For the past seven years a National Conference on Rural Health has been held under the auspices of a group in the American Medical Association known at first as the Committee on Rural Health and of late, The Council on Rural Health. Representatives of rural communities and physicians have gotten together to discuss rural needs and methods of meeting those needs.

This year's meeting of the Council will be held in Roanoke, Virginia, February 27-28. Dr. F. S. Crockett of Lafayette, Indiana, is chairman of the Council and will be among the speakers. Dr. Louis H. Bauer of Hempstead, New York, president of the AMA and Dr. John M. Travis of Jacksonville, Texas, who was chosen in December by the AMA as "General Practitioner of the Year," will also speak.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The regular meeting of the Minnesota Society of Neurology and Psychiatry was held at the Town and Country Club in Saint Paul, January 13. The scientific program for the evening included Dr. Richard W. Anderson speaking on, "The Use of Electroshock in the Treatment of Hysteria," and Drs. Sidney K. Shapiro and William T. Peyton presented the topic, "Spontaneous Thrombosis of the Carotid Arteries."

CONTINUATION COURSE

The University of Minnesota announces a continuation course in *Proctology* which will be held at the Center for Continuation Study from April 6 to 11, 1953. The course is intended primarily for physicians engaged in general practice. All aspects of ano-rectal diseases

will be covered, and two half-days will be devoted to operative clinics in which the registrants will take an active part. The visiting faculty will include Dr. Clarence Dennis, Professor and Chairman, Department of Surgery, State University of New York College of Medicine, New York City, who was formerly a member of the Department of Surgery at the University of Minnesota Medical School. The course will be presented under the direction of Dr. O. H. Wangensteen, Professor and Chairman, Department of Surgery; and Dr. Walter A. Fansler, Clinical Professor, and Director, Division of Proctology. The remainder of the faculty will include clinical and full-time members of the University of Minnesota Medical School and Mayo Foundation.

BLUE EARTH COUNTY SOCIETY

Dr. L. M. Hammar, of Mankato, was elected president of the Blue Earth County Medical Society at the annual meeting, held in December. Other officers elected were Dr. J. A. Butzer, Mankato, vice president; Dr. W. S. Chalgren, Mankato, secretary-treasurer; Dr. J. C. Vezina, Mapleton, delegate to the house of delegates of the state association, with Dr. R. G. Hankerson, Minnesota Lake, as alternate delegate. Dr. H. O. Morgan, Amboy, was elected to the board of censors.

ST. LOUIS COUNTY SOCIETY

Dr. R. P. Buckley of Duluth, succeeded Dr. P. F. Eckman as president of the St. Louis County Medical Society, January 8. Other officers installed at the annual meeting were Dr. M. O. Wallace, vice president; Dr. D. J. Van Ryzin, secretary-treasurer, and Dr. S. H. Boyer, Jr., president-elect for 1954. New state delegates were Drs. M. G. Gillespie and G. C. MacRae, with Dr. P. G. Boman and R. C. Pedersen as alternates.

The cost of preventable diseases imposes a staggering burden upon the human race. Every step that can be taken toward lessening this burden will not only diminish suffering and prolong human life; it will also increase productivity and promote prosperity.—C. E. A. Woman's Auxiliary

HENNEPIN COUNTY REPORTS ACTIVITIES

Mrs. Lawrence J. Leonard, President

The auxiliary year is already half over. Committee chairmen are alert and active and much has been accomplished. On October 3, the opening tea honoring officers and new members was held at the home of Dr. and Mrs. Elmer Rusten of Wayzata, which was attended by the state president, Mrs. C. L. Sheedy and some 230 members.

The November meeting included a silver tea for Sarahurst, which is a boarding home for discharged Glen Lake patients. On November 3, forty-nine members stuffed 24,000 Christmas Seal envelopes. The annual Glen Lake sale, November 13 and 14, held at Dayton's, netted $3,038.50. Members acted as salesladies and the Dayton Company donated space and services. The occupational therapist, Miss Lillian Bergren of Glen Lake Sanatorium, directed the sale of articles made by the patients and they, in turn, received the entire proceeds.

On December 8, the Auxiliary to the Minneapolis District Dental Society invited Hennepin County Medical Society auxiliary members to a tea at the home of Dr. and Mrs. Ralph Peterson. Over forty of the members attended this delightful event, which was carried out in a Hawaiian theme.

An auxiliary *News Letter,* now in its third edition, is receiving much favorable comment. Mrs. John Milton is the editor.

In Memoriam

FRED B. COLEMAN

Dr. Fred B. Coleman, formerly of Austin, Minnesota, died of leukemia at Long Beach, California, in November, 1952. He had retired and moved to California in 1934.

Dr. Coleman was born near Dodge Center, Minnesota, in 1874. He attended Hamline University, Saint Paul, and obtained his M.D. degree from the University of Minnesota in 1909. He was a member of the Mower County Medical Society, the Minnesota State Medical Association and the American Medical Association until 1934.

He served in the medical corps of the United States Army as a captain in World War I and was a fifty-year member of the Fidelity Lodge 391, A.F.&A.M. at Austin.

Surviving are two sisters, Mrs. Jessie A. Allen and Miss Helen A. Coleman, of Long Beach.

ASA J. HAMMOND

Dr. Asa J. Hammond, a resident of Minneapolis for forty-five years, died December 19, 1952, at the age of eighty-three.

Dr. Hammond was born at Lake City, Minnesota, May 8, 1869. He received his M.D. degree at the University of Minnesota in 1896 and practiced at Winnebago, Minnesota, from 1897 to 1907.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association and a member of the staffs of St. Barnabas and Eitel Hospitals. He was also a member of the Minneapolis Masonic Lodge.

Dr. Hammond is survived by his wife, Eva, and two daughters, Mrs. Kenneth E. Kelley, Minnetonka Beach, and Mrs. John Campbell, Hopkins.

RUTH G. NYSTROM

Dr. Ruth G. Nystrom, of Minneapolis, died December 12, 1952. She was fifty-three years of age.

Dr. Nystrom was born August 1, 1899, at Adel, Iowa. She received her medical degree from the University of Minnesota in 1927 and took postgraduate work in European clinics in 1928 and 1929. She practiced gynecology and obstetrics and neuropsychiatry in Minneapolis except for a year spent in Kalamazoo, Michigan, in 1941 and 1942. She was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Nystrom is survived by her mother, a sister and two brothers, all of Minneapolis.

WILLIAM C. RUTHERFORD

Dr. William C. Rutherford, formerly of Saint Paul, died in West Palm Beach, Florida, December 21, 1952.

Dr. Rutherford was born at Crookston, Minnesota, August 2, 1886. He obtained his medical degree from Marquette University, Milwaukee, in 1911 and practiced

SAMUEL LIEBMAN, M.S., M.D.

225 Sheridan Road **Medical Director** **Phone Winnetka 6-0211**

from 1911 to 1946 in Saint Paul. From 1918 to 1920, he served as a major in the Medical Corps of the United States Army.

He was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was a member of the American College of Surgeons and was the national medical examiner for the Degree of Honor Protective Association, Saint Paul.

In 1946, he moved to Nisswa, Minnesota, and opened an office at Brainerd. In recent years, he motored south where he spent his winters in West Palm Beach. While practicing at Brainerd, he was a member of the Upper Mississippi Medical Society, the Elks Lodge and local Knights of Columbus.

Dr. Rutherford was married to Claire Gibbons, who preceded him in death in 1943. Two half-brothers, Francis A. Jenne, of Saint Paul, and Charles Jenne, of Kansas City, survive him.

HAROLD ROBERT STOWE

Word has been received of the death of Dr. Harold Robert Stowe, former fellow in surgery of the Mayo Foundation, which occurred on December 1, 1952, at Council Bluffs, Iowa.

Dr. Stowe was born May 1, 1917, at Council Bluffs, Iowa. He attended the University of Omaha from 1934 to 1937 and received the degree of M.D. from the University of Nebraska in 1941. He interned at the Ancker Hospital at Saint Paul, Minnesota, from July, 1941, to October, 1942. He entered the Mayo Foundation as a fellow in surgery in October, 1947, and left the Mayo Foundation in December, 1951. He received the degree of M.S. in Surgery from the University of Minnesota on July 24, 1952.

Dr. Stowe was on active duty with the Medical Corps of the United States Navy from October, 1942, to July, 1947. He was a member of the Alumni Association of the Mayo Foundation.

KARL CHRISTIAN WOLD

Dr. Karl C. Wold, a well-known eye specialist of Saint Paul, died on December 24, 1952, at Princeton, New Jersey, where he was visiting his daughter, Mrs. Robert Johnson.

Dr. Wold was a native of Saint Paul, having been born there July 28, 1891. He graduated from the University of Minnesota Medical School in 1914 and interned at Bethesda Hospital, Saint Paul. He took postgraduate training at the Illinois Eye and Ear Infirmary, Chicago, and the University of Minnesota Department of Ophthalmology in 1915 and at the Chicago Eye, Ear, Nose and Throat Hospital in 1916.

Dr. Wold was a diplomate of the American Board of Ophthalmology (1923) and a member of the Minnesota Academy of Ophthalmology and Otolaryngology, serving as president of the Academy in 1945-1946. He was a Fellow of the American College of Surgeons (1924) and served as chief of staff at Bethesda Hospital three different times. He was an active member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. He served as a member of the Board of Directors of the Saint Paul Athletic Club from 1943 to 1945.

He lived at Dellwood, White Bear Lake, during the summers for many years and was captain of the White Bear Yacht Club for a number of years, taking a great interest in yacht racing activities. He also served as Commodore of the club.

Dr. Wold acquired considerable notoriety following the publication, in 1949, of his book entitled "Mr. President—How is Your Health." He became interested in the subject in 1941 and carried out considerable research for material for his book. His statement that President Franklin D. Roosevelt had suffered four strokes was denied by members of the President's family, but Dr. Wold did not retract his assertion. He advocated that before renomination presidents should undergo physical examinations by an impartial board.

Dr. Wold was a veteran of World War I. He is survived by his wife, Mabel, two sons, Dr. Keith Wold of Saint Paul and Sidney of Grand Forks, North Dakota; two daughters, Mrs. Robert Johnson of Princetion, New Jersey, and Mrs. John Strong of Austin, Minnesota.

Dr. Wold was an able oculist and his ability and pleasing personality procured him a large clientele and a host of friends.

Communication

To the Editor:

The American Cancer Society announces that the first four issues of its well-known monograph series are being reprinted. Copies of the following monographs will be available without charge to physicians in Minnesota:

1. *The Cancer Problem,* by Dr. Shields Warren
2. *Cancer of the Head and Neck,* by Dr. Hayes Martin
3. *The Diagnosis of Genitourinary Neoplasms,* by Dr. Victor F. Marshall
4. *Mouth Cancer and the Dentist,* by Dr. Hayes Martin

The Cancer Society has had thousands of requests for these monographs from physicians whose names were not yet on our mailing lists. Requests for back issues and future issues of the monographs may be made by writing the American Cancer Society, 295 North Snelling Avenue, St. Paul 4.

Yours very truly,

Of General Interest

Dr. Leslie C. Lane, ninety-seven, was honored in December as the oldest living graduate of the Rush Medical School of Chicago. Dr. Lane has practiced medicine in Minneapolis, Benson and Ortonville, since he came to Minnesota in 1861.

* * *

Dr. C. Kenneth Cook of Saint Paul, has been named chief of staff of St. John's Hospital for the coming year; Dr. T. S. McClanahan, White Bear Lake, vice president; Dr. C. R. Tifft, Saint Paul, second vice president, and Dr. Frank J. Milnar, Saint Paul, secretary, at the annual meeting of the medical staff, held December 8, 1952, at the hospital. **Drs. Francis J. Crombie** and **Robert W. Emmons**, both of Saint Paul, were named to the board of directors.

* * *

Dr. Neil D. Nickerson, Thief River Falls, attended a postgraduate course in gastroenterology at the University of Pennsylvania, the first week in December.

* * *

Dr. R. R. Remsberg, Tracy, attended the semi-annual McKennan Hospital staff clinic at Sioux Falls, South Dakota, December 3. The clinic program included discussion of modern trends in medicine generally, and the treatment of patients following radioactive warfare.

* * *

Dr. F. J. Hirschboeck, Duluth, a past president of the Minnesota Heart Association, spoke on the treatment of heart diseases to the twenty-eighth safety school, sponsored by the Duluth Chamber of Commerce Safety Bureau, held December 10, at the Hotel Duluth.

* * *

Dr. Sam H. Boyer, Jr., was named president-elect of the St. Louis County Medical Society at the meeting held December 11, at Duluth. **Dr. R. P. Buckley** was the incoming president and **Dr. Philip F. Eckman,** the retiring president.

* * *

Dr. Robert R. Kierland, consultant in dermatology and syphilology in the Mayo Clinic and associate professor in the Mayo Foundation, spoke on allergies at the eleventh annual meeting of the American Academy of Dermatology and Syphilology, held December 10, at Chicago.

* * *

Dr. M. Clifford Florine purchased the practice of the late **Dr. Clifford Wadd** (Dr. Wadd was killed in a highway accident in the fall of 1952) in Janesville and began practice in December. Dr. Florine is a graduate of the University of Minnesota Medical School and interned at Gorgas Hospital in the Canal Zone. From 1941 to 1945, he was with the engineering division at the Canal Zone.

A tour of the Variety Heart Hospital was conducted by staff doctors—**Richard Smith, Paul Winchell, Lewis Thomas** and **R. V. Ebert**—as part of the education program of the chairmen of the 1953 Heart Fund, at a meeting held at the Heart Hospital for fund drive orientation.

* * *

Dr. James A. Johnson, president, Hennepin County Chapter, American Cancer Society, and **Dr. Harold S. Diehl,** University Medical School dean, spoke at a cancer workshop December 8, held at Coffman Union on the University Campus.

* * *

Dr. Arthur Hunt, Rochester, was elected president of the Minnesota Obstetrical and Gynecological Society at its fall meeting, held December 6 in Minneapolis. He succeeds **Dr. John Haugen,** Minneapolis. **Dr. Arnold Swenson,** Duluth, was named vice president and **Dr. Rodney Sturley,** Saint Paul, was re-elected secretary-treasurer.

* * *

Dr. Frederick A. Figi, and **Dr. John B. Erich,** of the Mayo Clinic, won a first place award at the eleventh annual meeting of the American Academy of Dermatology and Syphilology for an exhibit on tumors of blood vessels.

* * *

Gifts totalling $300,000.00 for research and scholarships at the University of Minnesota were announced by the board of regents, December 12. The funds granted to further the interests of medicine were as follows:

Dr. John Wild was granted $21,616 to perfect instrumentation for the echograph, the ultrasonic device for detecting cancer.

Dr. F. John Lewis was granted $6,370 for additional experimental cardiac surgery.

Sharing in the $102,000 cancer grants from the United States Public Health Service, were **Dr. George Moore,** cancer co-ordinator, $25,000 for teaching and clinical work, and **Dr. Jerome T. Syverton,** head of the department of bacteriology and immunology, $15 000 for research on mouse mammary cancer and leukemia.

Also included in the United States Public Health Service grants were **Dr. Frederic Kottke,** head of the department of physical medicine, $18,078, and **Dr. Yoshio Sako,** fellow in surgery, $7,036.

* * *

Dr. E. H. Hartung, of Claremont, was selected physician for the Fairview Nursing Home by the Dodge County commissioners, at the meeting held December 2, at Claremont.

* * *

Dr. D. C. Balfour, Rochester, has been notified by the permanent secretary of the Académie Nationale de Médecine of France, that he was elected

Did you have any tax-exempt income in 1952?

TAXABLE INVESTMENT INCOME is your most expensive income since, under our progressive income tax system, it is this *"Top Layer"* income that pays the heaviest taxes.

There is little a taxpayer can do about his taxable income received from:

Professional Income
Salaries
Business Profits
Dividends from Business

These are main sources of revenues—your basic income. *"Top Layer"* income, however, your investment income, is something that you definitely have control over in that it is within your power to give such income either a "taxable" or a "tax-free" status.

The income from investments which is subject to taxation actually shrinks whenever your professional income increases and forces this taxable *"Top Layer"* income into a higher bracket. In other words, the more your active earning power is increased, the greater percentage of your taxable investment income will be paid out in taxes.

Interest income on Municipal Bonds is exempt from all present Federal Income Taxes and consequently provides a *"Top Layer"* income that remains constant regardless of changes in other income or tax rates.

The two following examples clearly demonstrate the effect of Federal Income taxes on *"Top Layer"* income:

If you are in the $12,000-$14,000 individual income tax bracket and purchase an investment to yield 3.00% you will realize about 1.55% if the income is taxable but will receive the full 3.00% if it is not taxable.

If you are in the $20,000-$22,000 individual income tax bracket and purchase an investment to yield 3.00% you will realize about 1.15% if the income is taxable but will receive the full 3.00% if it is not taxable.

We shall be pleased to send you information and descriptive circulars pertaining to Municipal Bonds.

Dr. Ralph E. Worden, former fellow in physical medicine of the Mayo Foundation, recently was appointed director of a new rehabilitation center at the Ohio State University at Columbus.

* * *

Dr. Mildred Schaffhausen, interning at Minneapolis General Hospital, was awarded the scholarship citation and $100 from the American Women's Medical Association, in December. Dr. Schaffhausen has had a 97.5 average during her four years at the University of Minnesota Medical School.

Officers for the coming year elected by the Freeborn County Medical Society at its annual meeting in December were **Dr. C. E. J. Nelson,** Albert Lea, president; **Dr. T. M. Hansen,** Albert Lea, vice president, and **Dr. L. E. Steiner,** Albert Lea, secretary-treasurer.

* * *

Dr. Robert I. Gruys and **Dr. John A. Watkins** opened a practice in Wells in December, in the former offices of Dr. W. H. Barr. Both Dr. Gruys and Dr. Watkins are graduates of the University of Minnesota Medical School. Dr. Watkins recently returned from Korea.

* * *

A new television set was donated to the Nopeming

Sanatorium at Nopeming by the Military Order of the Purple Heart, Duluth chapter, in December. **Dr. G. A. Hedberg**, chief physician, accepted the gift on behalf of the sanatorium.

* * *

Dr. A. J. Olson, Owatonna, was named chairman of the second Steele County x-ray survey program which will begin February 16.

* * *

"The Doctors Mayo," by Helen Clapesattle, editor of the University of Minnesota Press, was recently published in Brazil. The book was originally published in this country in 1941. The Portuguese edition was published under the book translation program of the United States Department of States international information administration.

* * *

Dr. Robert A. Stoy, Little Falls, was recalled to Army service in December. Dr. Stoy has been practicing in Little Falls since May, 1949, with **Drs. D. L. Johnson, Alfred H. Benson** and **William Skaife**.

* * *

Officers elected at the Fairmont Community Hospital's annual staff meeting were: **Dr. V. M. Vaughan**, Truman, president; **Dr. E. E. Zemke**, Fairmont, vice president, and **Dr. A. L. Ourada**, Ceylon, secretary-treasurer.

* * *

Dr. L. F. Johnston, Winona, attended the meetings of the American Academy of Obstetrics and Gynecology, held in Chicago, December 15 to 17.

St. Paul 1, Minnesota

* * *

Officers elected to the staff of St. Joseph's Hospital at Mankato at the annual meeting December 11, were: **Dr. A. A. Schmitz**, president; **Dr. J. A. Butzer**, vice president, and **Dr. J. C. Von Drasek**, secretary-treasurer. Members of the executive committee named were **Dr. M. I. Howard**, chairman, and **Drs. R. G. Hasset** and **J. A. Butzer.**

* * *

Dr. John Delmore of Roseau, was named to succeed **Dr. M. D. Starekow** of Thief River Falls, as president of the Red River Valley Medical Society, at the annual election meeting, held at Crookston, December 12. **Dr. Anthony Berlin** of Hallock, was elected vice president, and **Dr. R. O. Sather** of Crookston, re-elected secretary-treasurer. Delegate named to the Minnesota State Medical Association for a three-year term was **Dr. C. H. Holmstrom** of Warren, with **Dr. J. H. Cameron** of Crookston, as alternate. **Dr. W. W. Rieke** of Wayzata spoke to the group on public health measures in schools.

* * *

Axel C. Benson, "head doctor" for forty-two years at Swedish Hospital, will retire in March on his seventieth birthday and go to Florida. Mr. Benson has been "doctoring" heads of hospital patients at Northwestern and Mt. Sinai Hospitals, as well as Swedish Hospital during the last two years since his brother, who was also a barber, died.

* * *

The residence of the late **Dr. and Mrs. W. J. Mayo**, located adjacent to the Mayo Foundation House, will become an adjunct to the house, the Mayo Association announced in December. The house will be called Damon House in honor of Mrs. Mayo, whose maiden name was Hattie Damon.

Some of the rooms are being refurnished. Portraits of Dr. and Mrs. W. J. Mayo are being painted by Bjorn Egeli of Washington, D. C. The portraits, which will be gifts of **Dr. and Mrs. Donald C. Balfour, Sr.**, and **Dr. and Mrs. Waltman Walters**, will hang in one of the two houses.

* * *

Dr. Richard Carlton Lillehei, son of **Dr. and Mrs. Clarence I. Lillehei**, of Edina, and Betty Jeanne Larsen, of Minneapolis, were married December 20, in the Church of St. Stephen the Martyr at Edina. **Dr. C. Walton Lillehei**, University of Minnesota Hospitals, brother of the groom, was best man and **Dr. James P. Lillehei**, Veterans Administration Hospital, Ft. Snelling, another brother, was an usher. Both Dr. and Mrs. Lillehei were graduated from the University of Minnesota. Dr. Lillehei is a resident in surgery at the University Hospitals.

* * *

Dr. J. M. Gacusana, Hot Springs, South Dakota, will begin practice in Mahnomen, March 1. Dr. Gacusana served as an administrator of the hospital at White Earth for a period of time around 1945, so he is familiar with the Mahnomen area.

Among the founders of the nonprofit Hazelden Foundation are men who have recovered from alcoholism through the proved program of Alcoholics Anonymous and who know the problems of the alcoholic. All inquiries will be kept confidential.

HAZELDEN FOUNDATION

Lake Chisago, Center City, Minn. Telephone 83

Dr. Kathleen Jordan, of Riverside Sanatorium, Granite Falls, who is also a physician for the Christmas Seal organization, is busy with a tuberculin testing survey of the people of Lyon County.

* * *

Dr. Robert P. Meyer, Faribault, spoke at the regular weekly meeting of the Faribault Rotary Club, December 31. His subject was "The Detection of Cancer."

* * *

Dr. S. C. Blackmore, who has owned and operated the Bray Hospital at Biwabik for the last two years, has sold the buildings to Mrs. Harold Johnson, former county nurse in the area, who will begin operation of a private rest home early in 1953.

Dr. Blackmore will continue to have an office in the building and will maintain his practice as usual.

* * *

Dr. James Reinhardt, originally from Detroit Lakes, began practice in Alexandria early in January. Dr. Reinhardt received his medical degree from Temple University in Philadelphia in 1947, and completed his internship at Northwestern Hospital, Minneapolis.

* * *

Dr. Frank Heck, Mayo Clinic staff, was married to Dr. Louise M. Paul, Wakefield, New Hampshire, in December.

* * *

Dr. Wesley Spink, professor of medicine at the University of Minnesota, was one of ten doctors to receive awards for distinguished achievement in 1953 from *Modern Medicine*. Dr. Spink was cited for leading the development of preventive measures and treatment of brucellosis.

* * *

Dr. Orwood J. Campbell, Minneapolis, who became president of the Minnesota State Medical Association, January 1, will preside over the centennial celebration scheduled for this year in honor of the founding of the State Medical Association in 1853.

* * *

Dr. J. F. DuBois, Jr., Sauk Centre, was elected president of the medical staff of St. Michael's Hospital in Sauk Centre at the staff's annual meeting, held December 16. **Dr. A. H. Borgerson,** Long Prairie, was elected vice president, and **Dr. W. D. Cleaves,** Sauk Centre, secretary.

* * *

Dr. W. E. Herrell, of the Mayo Clinic staff, was quoted in an article appearing in the December issue of *The Ladies Home Journal.* Written by William L. Laurence, the article was entitled, "Lifesaving Drugs Can Harm You." What medical leaders in the field have said about the danger of indiscriminate use of the various antibiotics was emphasized throughout the article. A statement by Dr. Herrell, made at a meeting of the American Therapeutic Society in Chicago—"There is nothing wrong with the antibiotics—the trouble is with the people prescribing them," was quoted.

The Birches Sanitarium, Inc.

2391 Woodland Avenue
Duluth 3, Minnesota

A hospital for the care and treatment of Nervous and Mental disorders. Quiet, cheerful environment. Specially trained personnel. Recreational and occupational therapy.

Dr. L. R. Gowan, M.D., M.S., Medical Director

Dr. John Austin Culligan, Rochester, son of **Dr. and Mrs. John M. Culligan** of Saint Paul, was married to Miss Sheila Spriggs of Rochester, December 27, in Saint Paul. **Dr. John Phelan** of Duluth and **Dr. Bernard Spencer** of Rochester were two of the ushers. Dr. Culligan is on leave from a fellowship with the Mayo Foundation to serve with the navy medical corps.

* * *

The Estrem Clinic at Fergus Falls has now moved into a new, larger building and has a new name—the Park Region Medical Center. Medical staff of the center includes **Drs. Carl O. Estrem** and **Emmett A. Heiberg**, general medicine; **Dr. Glenn J. Mouritsen**, internal medicine and skin diseases; **Dr. Carl J. T. Lund**, obsetrics and gynecology; **Dr. Robert D. Estrem**, surgery; **Dr. Ralph L. Estrem**, internal medicine and x-ray, and **Dr. Rolf Daehlin**, children's diseases and obstetrics. An ophthalmologist is expected to join the staff in the spring.

* * *

Three Thief River Falls physicians—**Drs. Philip Parker, Forrest Rowell, Jr.**, and **Ted Bratrud**—will staff the Oklee Medical Clinic until a resident physician can be found. This arrangement began December 19.

* * *

Dr. D. C. Anderson, Olivia, was called back into active military service and closed his office December 26. He was assigned to the Naval Air Station at Pensacola, Florida.

* * *

Dr. Frank W. Reibold was elected president of the staff of St. Mary's Hospital, Duluth, at the staff meeting held December 24. Other officers named were **Dr. Joseph H. Weisberg**, vice president; and **Dr. Milton Finn**, secretary-treasurer.

* * *

"The Doctors' Roundtable," a WCCO-TV program on Sunday, December 28, featured **Dr. J. Arthur Myers**, professor of medicine and public health at the University of Minnesota; **Dr. John F. Briggs**, chief of medicine at Ancker Hospital in Saint Paul, and **Dr. Ezra V. Bridge**, superintendent of Mineral Springs Sanatorium, Cannon Falls. The doctors discussed diseases other than tuberculosis which are discovered as a result of chest x-ray programs.

Dr. George B. Eusterman, emeritus member of the Mayo Clinic staff, was appointed chief of medicine and director of education of Sinai Hospital in Detroit, Michigan, in December. Dr. Eusterman received his medical degree from the University of Minnesota in 1908 and joined the Mayo Clinic staff the same year.

* * *

Three new physicians on the Rochester State Hospital staff are **Dr. Frances M. Richards**, internal medicine, and **Drs. Conrad W. Baars** and **Ralph T. Taubert**, psychiatrists.

Dr. Richards was graduated from the University of Alberta, Canada, Medical School and interned at Minneapolis General Hospital.

Dr. Baars, a 1945 graduate of the University of Amsterdam, Holland, Medical School, came to the United States in 1946, on a fellowship to Lorrette Hospital, Chicago. He spent a year's residency in psychiatry at Minneapolis General Hospital and served fifteen months as psychiatrist and acting clinical director at Anoka State Hospital. Recently Dr. Baars returned from active military duty at the Specialized Medical Center, Camp Cooke, California.

Dr. Taubert was graduated from the University of Michigan Medical School in 1949 and then interned at Minneapolis General Hospital. He was on the staff of the Hastings State Hospital before coming to Rochester.

Drs. Donald and **Gloria Taylor** have resigned to go into private practice in San Diego and **Dr. D. E. McBroom** has retired.

* * *

Dr. A. J. Chesley, director, Minnesota State Board of Health; **Dr. W. W. Barr**, deputy director, and **Dr. Helen L. Knutson**, director of the division of hospital services, represented the State Board of Health at a meeting, held at Thief River Falls, December 17, to discuss the future of Oakland Park Sanatorium. Reorganization of existing facilities for care of tuberculosis patients over the state is under way.

* * *

Dr. Lewis Hanson, Frost, was recently appointed by the county commissioners to serve on the Faribault County Public Health Nursing Advisory Board as its medical director. **Dr. R. G. Hankerson,** Minnesota Lake, has been the medical director since the public health nursing service was established in 1946.

* * *

Dr. Howard R. Hartman, a member of the permanent staff of the Mayo Clinic since 1919, and head of a section in the division of medicine since 1938, retired from the Clinic, December 31. Dr. Hartman, who gained national recognition as an authority on the stresses and afflictions to which busy executives may be peculiarly susceptible, came to Rochester as an intern on July 1, 1914. He was graduated from the University of Michigan Medical School.

* * *

Many doctors from the area attended the doctors and editors Press-Radio-Medical dinner meeting, held at Brainerd, December 13. Discussion leaders for the program were **Dr. Hadden Carryer,** Mayo Clinic; Carl C. Carlson, Editor, *Long Prairie Leader;* Ed Tom O'Brien, Brainerd, owner of Radio Station KLIZ, and Manley Brist, Saint Paul, attorney for the Minnesota State Medical Association.

* * *

Dr. Donald Myhren Larson, Chicago, son of **Dr. and Mrs. Clarence Myhren Larson,** Minneapolis, was married to Miss Florence May Cadwell of Springfield, Illinois, December 27, at Chicago. **Dr. Roger Clarence Larson** of Washington, was his brother's best man.

Dr. E. T. Leddy, Mayo Clinic, addressed a meeting of the staff of the Veterans Administration Hospital in Grand Island, Nebraska, December 18, on "Some Combinations of Radiologic and Surgical Methods Worthwhile in the Treatment of Cancer."

* * *

Dr. J. C. Westenberger, of Austin, moved his offices from the downtown district to his residence in December. Dr. Westenberger has practiced medicine for fifty-five years and plans to retire soon. He will continue his practice for a time from his residential office, however.

* * *

Research grants approved upon recommendation of the National Advisory Arthritis and Metabolic Diseases Council of the Public Health Service for February, 1951 to June, 1952, totaled $1,743,839, some $670,000 being in the field of metabolism, $510,000 in arthritis research, and the balance scattered. Support has been provided for 170 research projects in seventy-nine institutions, located in thirty-two states, the District of Columbia, and three foreign countries. The National Institute of Arthritis and Metabolic Diseases which was established by Congress in 1950, within the Public Health Service is directed by Dr. Russell M. Wilder. Some seventy-eight beds in the new clinical center about to be opened at Bethesda, Maryland, have been allocated to this institute. In addition to this government-supported project the Arthritis and Rheumatism Foundation

is the principal voluntary agency devoted to the solution of the arthritis problem and it is supported by annual nation-wide fund-raising campaigns.

* * *

Dr. F. J. Hirschboeck and **Dr. Gordon Strewler** were elected directors of the David L. Tilderquist Memorial Library Association of Duluth, at the annual meeting, held January 8.

* * *

Dr. Carl B. Thuringer, Rochester, became associated in practice with **Dr. P. L. Halenbeck** and **Dr. Robert R. Petersen** in the Granite Exchange Building, St. Cloud, in January. Dr. Thuringer received his medical degree from the University of Oklahoma, interned at St. Anthony's Hospital in Oklahoma City and then spent two years in the army medical corps. In 1949, Dr. Thuringer entered the Mayo Clinic on a fellowship in general surgery which he recently completed.

* * *

Contributions to the American Medical Education Foundation in 1952 totaled more than $886,430. This includes the grant of $500,000 voted by the House of Delegates in December, 1951. An equal grant was voted by the House of Delegates in December, 1952. During the year 1952, 6,739 contributions were received from 6,697 individuals, eleven laymen, and thirty-one organizations. This was 4,863 more contributors than in 1951.

* * *

Dr. M. M. Hargraves, Mayo Clinic physician who is known for his knowledge and practice of land conservation, was featured in the *Saint Paul Sunday Pioneer Press* (Jan. 4, 1953, Pictorial Section) for his accomplishments aside from medicine. As a doctor, Dr. Hargraves is internationally known for his work on blood and bone marrow.

* * *

Dr. Milan E. Knapp of Minneapolis, spoke in Willmar, January 5, at a March of Dimes benefit supper given by the Kandiyohi County March of Dimes Chapter.

* * *

Dr. Robert H. Alway, a graduate of the University of Minnesota medical school, has been named chief of pediatrics at the National Jewish Hospital, Denver, Colorado.

Dr. D. C. Balfour, of the Mayo Clinic, who suffered a heart attack on Christmas Day, is recovering satisfactorily at the Worrall Hospital.

* * *

The National Foundation for Infantile Paralysis has been providing financial assistance yearly since 1949 to the Committee on Careers in Nursing which is endeavoring to recruit students for both professional and practical nursing schools. The grant this year will be $35,837. The work of the Foundation is handicapped by the lack of nurses, the shortage for civilian need alone being some 50,000.

* * *

Dr. Robert A. Rosenthal, Saint Paul pediatrician, spoke on "Medicine and Shakespeare" at the meeting of the senior members of the Women's City Club, held January 14, in Saint Paul. Dr. Rosenthal is a student of Shakespeare.

* * *

Dr. George Haggard, retired Minneapolis physician, was honored in the news recently for his long years of practice in Minnesota. Dr. Haggard was formerly a machinist and worked for the Milwaukee Road but decided to go to medical school, graduating at the age of thirty-six. In spite of his late start, Dr. Haggard conducted his medical practice for sixty years.

* * *

Dr. S. C. Blackmore, of Biwabik, lectured on heart disease at a meeting of the American Legion Auxiliary, January 20.

* * *

Dr. John J. Heisler, Richfield health officer, resigned in January to leave for service with the army medical corps.

* * *

The eighty-nine member chapters of the Muscular Dystrophy Association of America has just completed its second annual crusade to raise funds for research as to the cause of this disease, which is purported to affect more than 100,000 persons in the country, for the most part youngsters destined to die young. Muscular dystrophy research projects have been established in seventeen laboratories in the United States and abroad. This humanitarian project merits the support of the public. Contributions may be sent to local Chapters or to the Muscular Dystrophy Association, New York 8, New York.

* * *

Dr. John Mastin Travis, of Jacksonville, Texas, was named the General Practitioner of the Year by the House of Delegates at the clinical session of the AMA held in Denver in December. Dr. Travis, a general practitioner for the past forty-five years, has been most active in civic affairs, a leader in the promotion of public health and sanitation in the East Texas area particularly, and active in medical affairs.

* * *

Dr. Howard A. Rusk, director of the Institute of Physical Medicine and Rehabilitation of the New York University—Bellevue Medical Center, has been named as the 1952 winner of the $10,000 Dr. C. C. Criss Award and gold medal in recognition of his work in rehabilitating the physically handicapped. The award was established by Mutual Benefit Health and Accident Association of Omaha to honor outstanding contributors to the fields of health and safety. Winners in 1951 were **Dr. Edward C. Kendall,** bio-chemist, and **Dr. Philip S. Hench,** of Rochester. Awards are not limited to physicians, but Dr. Rusk was chosen from a list of some 150 nominees by a board of judges composed of prominent men and women in various fields, including **Dr. John W. Cline** and **Dr. C. W. Mayo.**

* * *

Dr. Owen H. Wangensteen, chairman of the University of Minnesota medical school department of surgery, spoke at the dedication of a new $450,000 hospital at Hudson, Wisconsin, January 18.

* * *

Dr. Frank G. Farley, joined the staff of the Adams Clinic at Hibbing in January. Dr. Farley is a graduate of Syracuse College of Medicine and served two years in the army medical corps. Recently he completed four years of specialized training in surgery.

* * *

Dr. Henry L. Taylor, of the University of Minnesota staff, spoke to the Braham Area PTA on "You, Your Heart and the Future," January 19.

* * *

Dr. H. W. Meyerding, of the Mayo Clinic, was elected to Fellowship in the New York Academy of Sciences at the annual meeting, held recently in New York City. Dr. Meyerding was honored in recognition of his outstanding scientific achievements.

* * *

Dr. George F. Allen, Veterans Administration Hospital, Batavia, New York, started as assistant medical director at Mineral Springs Sanatorium, January 3. Dr. Allen received his medical degree from the University of Rochester, Rochester, New York, and did research work in biological sciences at Johns Hopkins Hospital in Baltimore. He served in the army for three years, including overseas duty in the Pacific Theatre.

The Minnesota Society for Mentally Retarded, of which Mr. Walker Groetzinger is president, is a member of the National Association for Retarded Children which was founded in 1950 and now has 129 units in thirty-three states and the District of Columbia. The National Association recently named Dr. Grover F. Powers, Professor Emeritus in Pediatrics, Yale University, chairman of a twenty-five member national board composed of eminent scientists in the country to direct research on mental retardation. Dr. Powers, an internationally recognized child specialist, teacher and researcher is a consultant of the American Academy of Pediatricians, of which he is a Fellow.

* * *

BLUE CROSS-BLUE SHIELD

By the beginning of 1953, in slightly more than five years of its existence, Minnesota Blue Shield has enrolled over 560,000 subscribers or approximately one-fifth of the entire population of the state. During this same period it has paid over $10 million to the medical profession for the subscribers' medical benefits. It now has almost 2800 participating physicians in Minnesota, and it processes practically 10,000 claims a month. During its brief span of life it has increased its benefits to subscribers on four separate occasions and has raised its rates only once and that a minimum amount for only two types of contract holders. This briefly establishes the salient features of Blue Shield's progress in Minnesota to date.

As the number of its subscribers passed the half million level, Minnesota's plan has now become the eleventh largest Blue Shield Plan in the country. Despite this, its present enrollment is only slightly more than one-half that of its companion organization, Minnesota Blue Cross, which indicates that the saturation point is not close at hand and that Minnesota Blue Shield is still a lusty, growing organization. In other words, the present enrollment in Blue Shield is not the end but merely the start of prepaid medical coverage, and every effort is to be put forth to extend to as many residents of the state as is possible the benefits which are provided by the Blue Shield plan.

Steadily increasing payments of claims or benefits are not only the result of the growing number of subscribers, but are also related to the increases in benefits or fees which recently went into effect. It is noteworthy that the number of claims processed per month has more than doubled since August, 1950, and through that same period the amount of money paid for medical benefits each month has almost doubled. With increases of fees or benefits for almost 100 of the total 1000 items of the Schedule of Payments having been made effective several months ago, it is to be expected that the amount of money paid to doctors as medical benefits will increase even more rapidly than before.

Another facet of Blue Shield's development which merits consideration is its slow yet steady increase of participating physicians. In spite of the fact that during the past two years over 100 of Minnesota's participating physicians have entered the military service there are now about fifty more participating physicians than two years ago. In fact, with 2800 Minnesota doctors having signed the participating agreement, it can be said that, with the exception of one large group, less than 100 practicing physicians of the state have failed to affiliate themselves with the Minnesota Blue Shield program.

With these developments, it is evident that Blue Shield is playing a prominent role in the general scheme of medical care in Minnesota. An ever-expanding segment of the state's population obtains a greater portion of its medical care bill through Blue Shield. Continuing and even more energetic or at least more articulate support and promotion of the Blue Shield program by the doctors of the state should lead to more and better care for the people and greater prosperity for those who provide the care.

Blue Shield payment for surgical-medical care of Minnesota Medical Service incorporated participant subscribers:

For 12 months of 1951	$3,095,213.00
For 11 months of 1952	$3,337,875.00

Blue Cross payment for hospital care of Minnesota Hospital Service Association participant subscribers:

For 12 months of 1951	$11,312,390.00
For 11 months of 1952	$11,370,458.00

ENDOCRINE TREATMENT IN GENERAL PRACTICE. Edited by Max A. Goldzieher, M.D., and Joseph W. Goldzieher, M.D. 474 pages. Illus. Price $8.00, cloth. New York: Springer Publishing Co., 1953.

CLINICAL OBSTETRICS. Edited by Clifford B. Lull, M.D., Late Director, Division of Obstetrics and Gynecology, Pennsylvania Hospital; and Robert A. Kimbrough, M.D., Director of the Division of Obstetrics and Gynecology, Pennslvania Hospital, Professor of Gynecology and Obstetrics, Graduate School of Medicine, University of Pennsylvania, Gynecologist to the Graduate Hospital. 732 pages. Illus. Price $10.00, cloth. Philadelphia: J. B. Lippincott Co., 1953.

THE LITERATURE ON STREPTOMYCIN, 1944-1952. Compiled by Selman A. Waksman. 2nd ed. 553 pages. Price $5.00. New Brunswick, N. J.: Rutgers University Press, 1952.

Who could be more competent to compile a bibliography on streptomycin than Selman A. Waksman, who has just recently been awarded the Nobel Prize in medicine and physiology for "his discovery of streptomycin, the first effective antibiotic against tuberculosis?"

The first edition of this bibliography appeared in 1948 when the references on streptomycin numbered nearly 1,200. Now there are nearly 6,000 on this subject. To keep this bibliography up to date, the present plan is to publish annual supplements to this volume.

Dr. Waksman explains in the preface the scope of this comprehensive bibliography and the policy of inclusion or rejection of references which guided him.

The references are arranged in as nearly chronological order as possible. Articles which were important forerunners to the discovery of streptomycin are listed first. They are numbered in Roman numerals. The rest are numbered in Arabic numerals. Number 1 is given to the first paper in which the isolation of streptomycin was announced in 1944.

There are two excellent indices to the bibliography. One is the complete author index; the other is a subject index, which is quite detailed.

Dextri-Maltose
MEAD
No 1

For routine infant feeding. The basic Dextri-Maltose product.

Dextri-Maltose

MEAD

MEAD JOHNSON & COMPANY
Evansville 21, Ind., U.S.A.

Dextri-Maltose
MEAD
No 2

Especially indicated for premature infants. Contains 50 mg. ascorbic acid per ounce.

Dextri-Maltose
MEAD
No 3

To aid in counteracting constipation. Contains 3% potassium bicarbonate.

designed with singleness of purpose

Designed and manufactured specifically for infant formulas,
Dextri-Maltose® has an unequaled background of successful clinical use.
Safety for your infant patients is assured by the dry form of
this carbohydrate, meticulous laboratory control at all stages in its
manufacture, and hermetically sealed, key-opening cans.
Dextri-Maltose is palatable but not sweet; does not
create a "sweet tooth" in infants.
Easily measured without spilling or waste and almost instantly
soluble, Dextri-Maltose is convenient for the mother.

Chloromycetin®

in the pneumonias

Chloromycetin is rapid in producing defervescence and recovery, according to recent comparative studies.

exceptionally well tolerated, CHLOROMYCETIN is noted for the infrequent occurrence of even mild gastrointestinal and other side effects.

Serious blood disorders following its use are rare. However, it is a potent therapeutic agent, and should not be used indiscriminately or for minor infections — and, as with certain other drugs, adequate blood studies should be made when the patient requires prolonged or intermittent therapy.

Chloromycetin (chloramphenicol, Parke-Davis) is available in a variety of forms, including: Chloromycetin Kapseals,® 250 mg., bottles of 16 and 100. Chloromycetin Capsules, 100 mg., bottles of 25 and 100. Chloromycetin Capsules, 50 mg., bottles of 25 and 100. Chloromycetin Ophthalmic Ointment, 1%, ⅛-ounce collapsible tubes. Chloromycetin Ophthalmic, 25 mg. dry powder for solution, individual vials with droppers.

The Balance Sheet

We are all striving mightily to set aside some portion of our income in reserve. This is not an easy task in this day of heavy taxation. Yet these reserves are important; to be used for contingencies that we cannot predict today. It's silly to be forced to stand idly aside and watch those reserves being dissipated through protracted periods of disability when you could have prevented it by the purchase of an outstanding Disability Policy.

It's only logic that indicates that your best plan of income protection is through the plan available to you through your Association.

Tomorrow may be too late—ACT NOW.

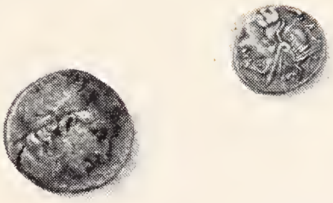
Number 3 of a series on the human meaning of great discoveries.

SMALL CHANGE



To achieve change is man's historic mission. To count change is an ordinary matter. But the coins which we give or receive a dozen times a day represent one of history's great inventions. Before money was invented, merchants had to carry bars of metal or sacks of grain, with scales and weights. The first coins minted in Asia Minor in the seventh century B.C. were too valuable for ordinary transactions. The epoch making social transformation came in Greece with the invention of small change. Then the farmer could buy an iron pot or sell a dozen eggs. The laborer could spend his wages in the marketplace. When we count our change, it may not be amiss to count our blessings. These modest tokens facilitate the large-scale interchange of goods and services on which our civilization is built. The penny tends to vanish. The dime becomes thinner. But the value of man's inventive genius is beyond calculation and beyond price, performing new miracles to meet new needs.

Meat...

and the Weight Reduction Diet in Cardiac Disease

The important relationship between obesity and the outlook in cardiac disease and hypertension is vividly emphasized in a recent publication of The American Heart Association.*

For reasons not entirely understood at present, "heart disease and high blood pressure are more common in overweight persons than in those of desirable weight." The predisposition to atherosclerosis in obesity and the increased physical burden of carrying excess weight are undoubtedly contributing factors. Hence, as this publication points out, weight reduction is the first line of defense in decreasing the incidence of cardiac disease, and in improving the prognosis after cardiac disease or hypertension has developed.

Meat occupies a prominent position in the weight reduction diets outlined in this American Heart Association booklet. This recommendation is in sharp contrast to the erroneous belief held in former years that meat is harmful in hypertension or cardiac disease. "There is no evidence that red meat or any other form of protein in moderation has any adverse influence on blood pressure."

The magic formula for reducing is simply "Eat less." Two types of diets are outlined. One "allows moderate amounts of meat and other proteins, small amounts of fat and moderate amounts of carbohydrates." The other is "high in protein with plenty of meat, eggs and cheese, moderate in fat and low in carbohydrates." Diet No. 1 provides 70 Gm. of protein, 60 Gm. of fat, and 120 Gm. of carbohydrate; caloric yield, 1,300. Diet No. 2 provides 100 Gm. of protein, 80 Gm. of fat, and 60 Gm. of carbohydrate; caloric yield, 1,360.

The inclusion of generous amounts of meat in these diets—12 to 16 ounces of cooked meat or two substantial servings each day in Diet No. 2—is a reflection of the important role meat plays in any weight reduction regimen. It is generously included because of its high content of protein of excellent biologic value and because lean meat contains unobjectionably small amounts of fat.

AN APPROACH TOWARD THE IDEAL IN PARENTERAL NUTRITION

J. H. STRICKLER, M.D. and CARL O. RICE, M.D.

Minneapolis, Minnesota

IN ORDER that homeostasis be maintained when parenteral nutrition becomes necessary, it would seem reasonable that an artificial or parenteral food should supply elements resembling normal constituents as closely as possible. Such a solution has been prepared and it is the purpose of this paper to evaluate its effectiveness in terms of fluid, nitrogen, and electrolyte balance studies.

A solution of 12 per cent invert sugar, 6 per cent amino acids and 4 per cent alcohol constitutes 1,000 calories per liter and very closely approximates the average normal proportion of food substances in terms of calories as outlined by Best and Taylor[8] in that it contains 48 per cent carbohydrate, 24 per cent protein and 28 per cent fat substitute, or alcohol.

The calorie as a unit of energy may be figuratively considered as a matrix holding the food substances in balance. Many authors have exhibited concern over the absence of calories in present day parenteral nutrition.[10,9,55,41,23,59,57,36,19]

Fluid balance is related to proper nutritional intake.[7] The electrolyte problem is likewise complicated by inadequate caloric intake.[26,41,20,21,56,55]

In scrutinizing the numerous nitrogen balance studies, it is evident that the absence of a standard caloric intake inserts a very large variable that is not considered in most studies. This variable factor likely accounts for disparity in observations. Furthermore, the investigators who have striven for adequacy of caloric supplement have rather consistently achieved a positive nitrogen balance[23] even to the extent of denying the presence of the so-called catabolic impulse of trauma. A good many workers[9,2,5,55,10,17,14,46,56,22,41,60,44,12,36,34,15,16,20,38,19] have all conducted studies bearing upon or demonstrating the need for caloric protection of protein or amino acids.

W. C. Rose[53] found the normal male required forty-five calories per kilogram to obtain nitrogen equilibrium and that fifty-five calories per kilogram were needed to bring about a positive nitrogen balance. Increasing glucose intake also decreases ketone excretion in the urine.[61,42,18]

Glucose as a means of supplying calories has the limitation of producing glycosuria and diuresis when administered in higher concentrations. Fructose and invert sugar appear to considerably improve these limitations since fructose is more rapidly converted to liver glycogen, has considerably less urinary loss and less diuresis. Hydration[3] and nitrogen retention[1] appear to be better on fructose administration than glucose. More rapid utilization appears to be due to more rapid phosphorylation.[13,58] In spite of a low renal threshold for fructose, there is less urinary spillage than from glucose. This is apparently accounted for by the more rapid utilization of fructose.

Fat emulsions have been extensively studied.[55,22,38,15,39] The problems of pyrogenic and hemolytic reactions following storage have not as yet been solved.

Ethyl alcohol contains seven calories per gram, or 5.6 calories per cc. and must of necessity be burned for energy or excreted since alcohol cannot be stored by the body. Ten cc. of absolute alcohol per hour can be metabolized.[27] When

---

Presented before the Minneapolis Surgical Society as part of a Symposium on Fluid Balance and Related Problems in Surgical Patients, March 6, 1952.

alcohol and glucose are given together,[24] alcohol is apparently burned in preference. Several investigators[43,4,11,35,27,32,37] have noted the caloric advantages of alcohol and this protective influence upon the nitrogen balance has been demonstrated by nitrogen balance studies.[48,49,50,51]

One investigator found an increased gastric hydrochloric acid on intravenous alcohol,[40] but another[50] found an identical slight increase on any of several types of intravenous infusions.

It would appear that most all investigators agree that alcohol will not damage the liver if nutrition is adequate.[9,28,30,45,52]

Any parenteral nutrition and particularly a more complete supplement should be administered slowly in order that the circulatory system and fluid compartments not be loaded too quickly and that fluid and electrolyte shifts be not induced by rapid loading. Lusk[31] has demonstrated a reduction of specific dynamic action to zero by small, very frequent feedings of a balanced mixture of oral food. An efficient, practical method of administering a balanced parenteral nutrition is by means of a polyethylene plastic venous catheter as first described by Zimmerman.[62]

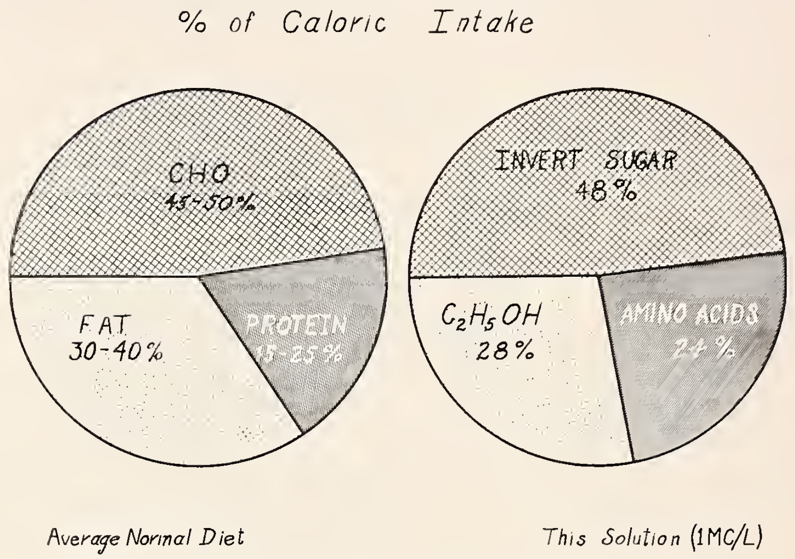

Fig. 1. Per cent of caloric intake.

TABLE I.
SOLUTION CONTAINING 1000 CALORIES PER LITER

	Grams	Caloric Value	Proportion of Calories	
			This Solution 1M C/L	Ideal
Invert Sugar (Carbohydrate)	120 gms.	480 C	48%	45-50%
Amino Acids (Protein)	60 gms.	240 C	24%	15-25%
Alcohol (Fat Substitute)	40 gms.	280 C	28%	30-40%
H_2O (Sufficient quantity)	1000 cc.			
Total		1000 C	100%

Amino Acids	150	600	24%
Alcohol	100	700	28%
Cal. Balance		100%	

The solution under investigation in this study contains 1,000 calories per liter, in percentages, as indicated in Figure 1 and Table I.

By calculating the basal caloric requirement from DuBois chart and making sufficient addition (approximately 30 per cent) for bed activity and making addition for specific dynamic action requirement at 8 per cent and then adding 8 per cent more for each degree of temperature above normal, the metabolic requirement can be calculated for each patient and his parenteral nutrition ordered accordingly.

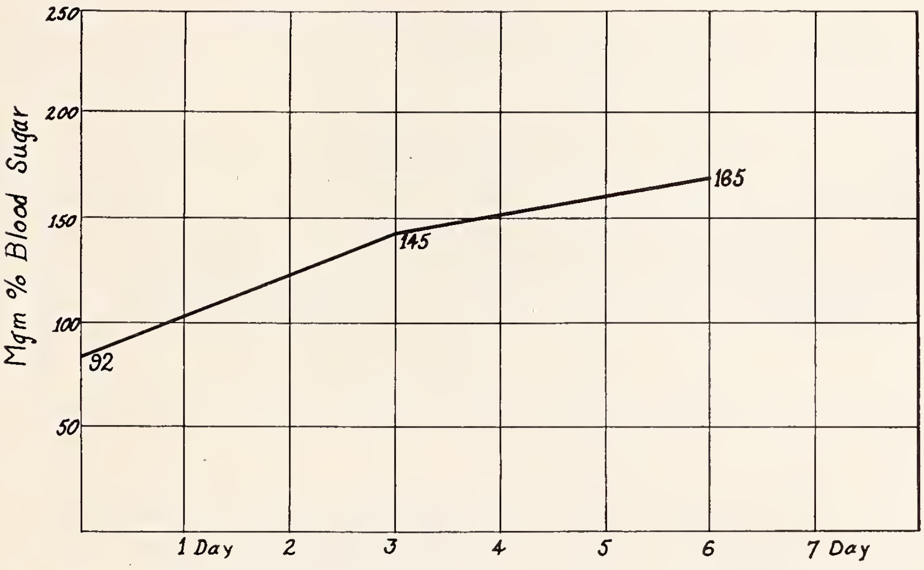

Fig. 2. Blood sugar elevation during continuous administration of a solution containing 1000 calories per liter (invert sugar, 12 per cent; amino acids, 6 per cent; alcohol, 5 per cent).

TABLE III.

Percentage Loss of Sugar in Urine—57 Cases 1M C/L

Day	—4	—3	—2	—1	Day of Surgery	+1	+2	+3	+4
Per Cent	3.9	4.6	4.7	4.6	9.2	6.7	6.5	5.2	6.4

Total Average Loss in 237 days (57 cases) Quantitative Urine Sugar = 5.96%

In addition to meeting the average normal urine output of 1,000-1,500 cc. daily one should calculate and administer a quantity of fluid equivalent to the insensible loss. Darrow has established a method of calculating this loss by employing the factor of 44 cc. of insensible fluid loss per 100 calories metabolized by the individual. If one will then calculate the metabolic requirement in calories by the DeBois chart, it is then also possible to quickly calculate the insensible loss. For a normal individual it is readily seen that one must give about 1 cc. of fluid for each calorie metabolized. The converse is likely true that if one gives the optimal caloric nutrition, the ideal solution should contain 1 calorie per cc. or 1,000 calories per liter.

Table II demonstrates the comparison of various types of parenteral fluid administered at an intake level of 2,500 cc.

In the treatment of a surgical patient, particularly one who has gastrointestinal suction or fistulae losses, such losses must be calculated daily and added to the fluid intake. Likewise, additional fever demands greater fluid intake. It also introduces the requirement for a greater number of calories and thus, as both fluid and caloric requirements are increased, the proper fluid administration by the 1,000 calorie solution will, in the main, also meet the caloric demands of the patient.

Since it is desirable to inject any parenteral alimentation slowly in order that the fluid load upon the circulation is not excessive and in order that the proffered constituents be fully utilized, and since a needle by the usual method would be impractical for a twenty-four-hour period, the desirable ideal is met by use of a polyethylene tube inserted through a No. 15 needle into the basilic vein of the antecubital fossa.

A continuous infusion of solution containing 1,000 calories per liter over several days of time has been followed by numerous methods of study to determine its effect upon the patient's physiologic processes.

Figure 2 demonstrates the effect upon the blood sugar level over the course of a six-day period during which time blood sugar levels have been taken while the intravenous administration is in progress.

Table III describes, in table form, the percentage loss of sugar in the urine during continuous administration of the 1,000 calories per liter solution. Attention may be called to the increase of urine sugar loss on and following the day of operation. This is likely due to the so-called temporary diabetes of trauma and in our opinion represents the standard response to stress.

The blood alcohol levels followed at varying speeds of injection are demonstrated in Figure 3. It may be noted that even though the alcohol administration rate is at a level of 20 cc. per hour a drunkenness level of .15 is not attained. A sedative level at .08 has however, been reached. If the usual rate of administration of the 1,000 calorie per liter solution containing 4 per cent alcohol and administered at a rate of 3,000 cc. in twenty-four hours, or a liter every eight hours, the rate would be roughly 6 cc. per hour, a rate which uniformly gives an almost negligible blood alcohol level. Since the average person can metabolize 10 cc. of absolute alcohol per hour without appreciably elevating the blood alcohol level, we would not anticipate any of the side effects of alcohol.

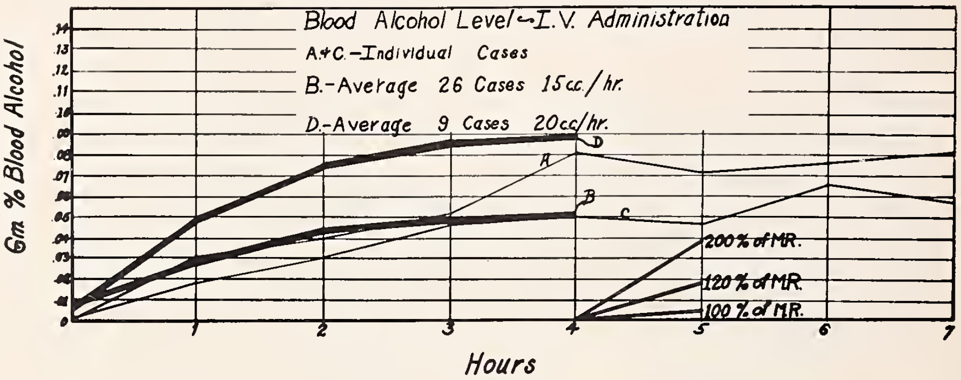

Fig. 3. Blood alcohol level during continuous intravenous administration of alcohol in saline.

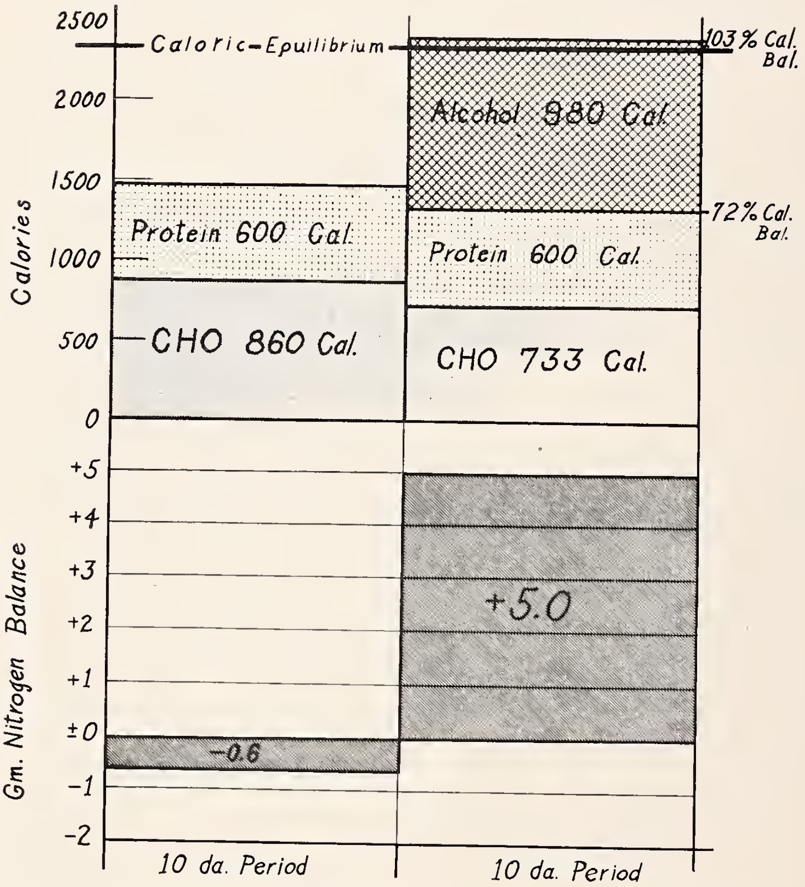

Fig. 4. Nitrogen balance as influenced by the addition of alcohol.

On the same Figure 3 can be seen another representation of the effects of alcohol administration in terms of metabolic requirements. It will be noted that if alcohol is given at the level of metabolic requirement, it will not exceed .01

gms. per cent level. It is only when the metabolic requirement is exceeded that the blood alcohol level will rise.

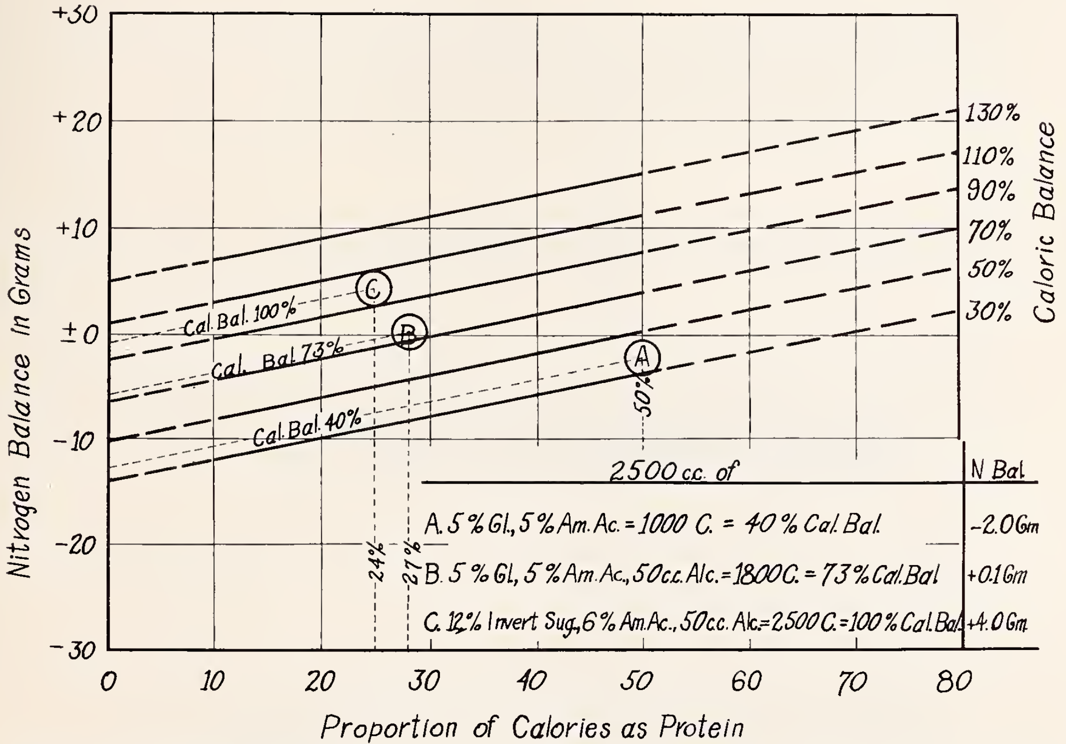

Fig. 5. Range of nitrogen balance in relation to caloric balance depicting three different parenteral solutions.

Since one of the prime purposes for the addition of alcohol and invert sugar to parenteral alimentation is to protect the amino acids from being burned as energy calories and making them available for tissue synthesis, it is therefore important that we scrutinize the influence of such additional calories upon the nitrogen balance. In Figure 4 it may be seen that the addition of alcohol calories brings the patient into caloric equilibrium and a positive nitrogen balance.

Variations in nitrogen balance were observed in many instances and were almost always explainable on the basis of the nitrogen or caloric intake in relation to the metabolic requirements of the patient. Analysis of 298 separate daily nitrogen balance studies revealed variations from time to time which could not be adequately explained until the caloric balance was also taken into consideration. Then when a constant nitrogen and caloric intake was maintained for several days as the patient's condition remained constant, a change in either the caloric or nitrogen intake in relation to the caloric requirement caused a change in the nitrogen balance. It is also evident in the following figure that when the patient was essentially in caloric equilibrium, no difficulty was encountered in obtaining a positive nitrogen balance with an average amount of nitrogen intake. On the other hand, when the patient was in negative caloric balance, he was also in negative nitrogen balance unless the nitrogen intake greatly exceeded the average normal allowance.

By a statistical analysis of three variable factors—caloric balance, nitrogen balance and percentage of protein calories—on a three dimensional association defined in terms of two variable scatters for a series of short limited range of the third variable, it thus became clear that the three variables were all intercorrelated. Figure 5 demonstrates this correlation in a graphic manner.

On the basis of 2,500 cc. of fluid with the percentage of caloric requirements derived from three separate solutions (5 per cent glucose in 5 per cent amino acids; 5 per cent glucose with 5 per cent amino acids and 5 per cent alcohol, and 12 per cent invert sugar, 6 per cent amino acids and 4 per cent alcohol). Figure 5 reveals the influence upon the nitrogen balance in terms of the usual normal fluid requirements. When represented in this way it may be seen that only the 1,000 calories per liter solution can easily attain a positive nitrogen balance without exceeding the normal fluid intake.

Daily blood electrolyte determinations on patients receiving a constant infusion of 1,000 calories per liter solution reveal that a composite or group average fall well within the limits of normal values, thus indicating that a normal electrolyte pattern for homeostasis is maintained. The physiologic ideal is then more closely approached (Figs. 6 and 7).

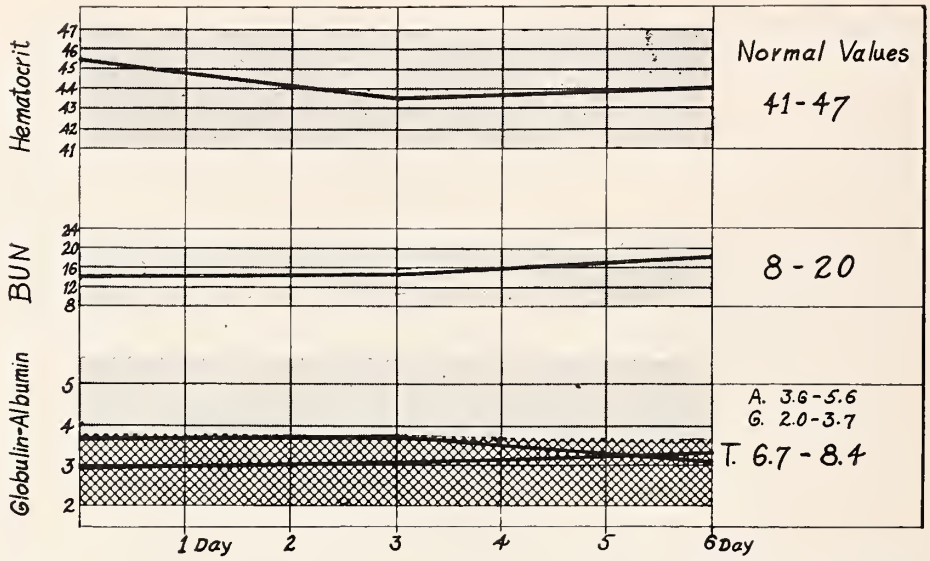

Fig. 6. Blood electrolyte status during administration of a solution containing 1000 calories per liter (invert sugar, 12 per cent; amino acids, 6 per cent; alcohol, 5 per cent).

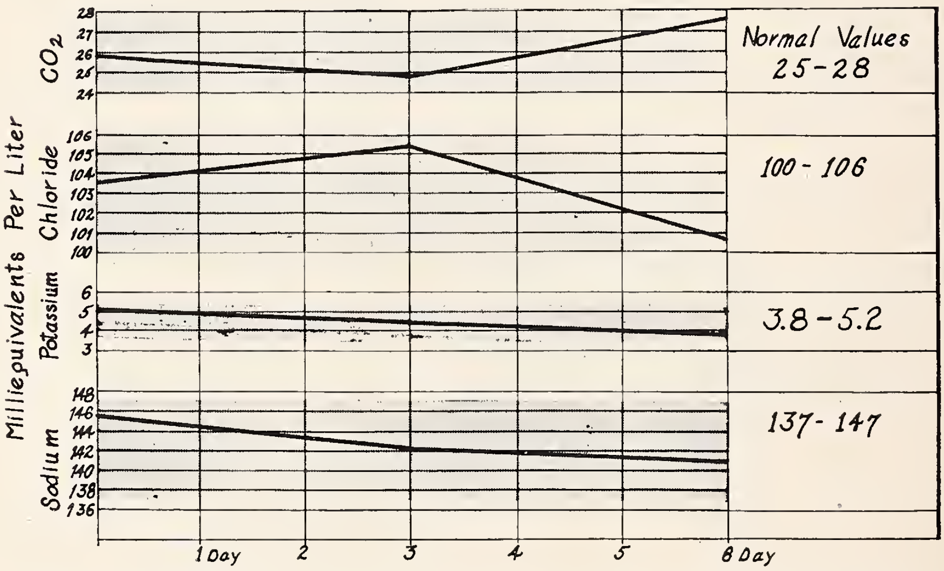

Fig. 7. Blood electrolyte status during administration of a solution containing 1000 calories per liter (invert sugar, 12 per cent; amino acids, 6 per cent; alcohol, 5 per cent).

A most natural inquiry would be, "Can this solution be tolerated by the tissues or in the blood stream at any point where it might infiltrate or meet the blood flow prior to dilution?" The pH of this solution is 5.55 and, although quite acid, has not caused undue reaction in the tissues when infiltrated out of the ordinary intravenous needle. The reaction might be classified as being halfway between that of 5 per cent and 10 per cent dextrose. A phlebitis has been produced but likely not as frequently as that of higher percentages of glucose. When introduced in the desired manner by way of a polyethylene catheter into an arm vein, the only reaction noted is from the polyethylene tube itself. This reaction at the site of entrance of the tube and ascending phlebitis constitute somewhat of a problem which however does not outweigh the advantages of constant comfortable fluid administration. Cautious attention to technique of venous catheterization is apparently the answer to minimizing phlebitis. If the tube is changed to another vein at the earliest sign of phlebitis, then only a very minor reaction is caused.

In order that an assessment of the possible damaging effect upon blood cells at the point of mixture of the solution and blood could be made, an experiment was set up resembling that of the fragility test. Various solutions were compared (Fig. 8).

A final demonstration of the ability of proper and complete parenteral alimentation may be demonstrated from the Figure 9 representing the

postoperative course of a patient who had a Whipple resection for carcinoma of the ampulla of vater. It may be seen that almost all of her studies showed a nearly perfect balance and that her clinical course described by the fever chart and the ability to resume complete oral food intake by the sixth postoperative day, indicated rapid surgical recovery.

Conclusions and Summary

1. A solution containing 12 per cent invert sugar, 6 per cent amino acids, 4 per cent alcohol furnishes 1,000 calories per liter and approaches the ideal proportion in terms of normal human intake of the various food substances.

2. Invert sugar can be used in greater concentration without producing as much hyperglycemia or glycosuria as is produced from equivalent percentage of glucose.

3. The blood alcohol elevation is almost negligible at the recommended infusion rate.

4. Additional evidence has been presented supporting the thesis that parenteral protein requires adequate caloric intake for optimal utilization of the amino acids.

5. Slow, continuous, around-the-clock infusion through plastic venous catheter affords best utilization of all constituents of parenteral alimentation.

MEDICAL SCHOOLS IN FINANCIAL NEED

American medical schools need an average of $250,000.00 more each year in order to do a really first-rate job, according to Dr. Ward Darley, president of the Association of American Medical Colleges and vice president and dean of the department of medicine at the University of Colorado.

Chief cause of the financial crisis, according to Dr. Darley, is the 500 per cent increase in operating costs of the medical schools over the past thirty years. Aside from the increased costs of educating medical students, the medical schools also are called upon to help in the instruction of many kinds of health personnel other than future doctors, furnish medical services to the community, and support extensive research activities in order to keep pace with the constantly advancing field of medical science.

Our changing economy also has a part in contributing to the difficulties of the schools, Dr. Darley says. Although in 1941, 35 per cent of the schools' income came from endowment interest, this percentage dropped to 20 per cent in 1948 despite a 21 per cent increase in endowment capital.

While not recommending any single course of action, Dr. Darley summarizes the various ways in which medical schools can brighten their financial picture. These include selling medical and hospital services, increasing community support for operation of teaching hospitals and clinics, recovering the actual costs involved in research programs, receiving larger city and state appropriations, soliciting more and larger gifts, grants and endowments, increasing tuition and, perhaps, accepting federal subsidy.

Dr. Darley noted that in reference to increasing tuition, charges are now an average $623 annually, an increase of 165 per cent since 1939. Increases in tuition will further overburden the financial resources of most students.

THE DIAGNOSIS AND MANAGEMENT OF PERIPHERAL ARTERIAL EMBOLISM

JOHN L. KEELEY, M.D.

Chicago, Illinois

An arterial embolus is a blood clot which usually arises in the heart and is carried peripherally by the blood stream to occlude a femoral artery. Although this is not true in all cases, Danzis[7] found it to be so in over half of 129 cases studied, and more recently Haimovici[16] in a study of 330 unselected cases of peripheral arterial emboli found the heart to be the source of the clot in 96 per cent and a lower extremity the site of lodgement in 84 per cent. Details of etiology, variations in behavior, other sites and degrees of arterial obstruction and, finally, management and prognosis form the basis of this article.

The various sites of origin have a bearing on the physical nature of emboli and are worth considering in detail. The unusual sites of origin and the unusual types of emboli will not be overlooked if the various segments and divisions of the circulation are considered in physiologic order. Paradoxical emboli are those arising from the peripheral venous system as a result of intravascular clotting or the liberation of a portion of a tumor but they can reach the arterial side only if there is a defect in the partition between the right and left heart chambers. Passage of emboli through interventricular septal defects and patent foramena ovale have been reported.[1,18,19,20,24,32] Emboli arising from the pulmonary circulation have been reported and include clot from an area of injured lung and portions of tumor swept away from either a primary[5,36] or metastatic[15] pulmonary lesion. A tumor embolus originating from a primary myxoma of the left ventricle causing occlusion of the renal arteries and the aortic bifurcation has been reported.[40]

Mural thrombi are the most common sources of emboli. In those arising from the left auricle rheumatic heart disease with mitral stenosis is usually present. Mural thrombi in the ventricles are more frequently found on the left and are associated with myocardial infarction in 90 per cent of the cases. Vegetations from the mitral valve in the course of subacute bacterial endocarditis more commonly cause visceral embolic disturbances rather than obstruction of a larger peripheral artery. Uncommonly an arteriosclerotic plaque from the wall of the aorta may become detached and be carried peripherally.

Association of heart disease and peripheral arterial embolization is frequent. McKechnie and Allen[30] found heart disease in forty-one of forty-six patients with peripheral arterial emboli; Willius[39] found emboli in 30 per cent of patients dying of mitral stenosis and cardiac failure; Garvin[12] found mural thrombi in thirty-seven of 116 autopsies in rheumatic heart disease. The heart was the source of the peripheral arterial emboli in 60 per cent of the cases in the extensive review of the literature in 1933 by Danzis,[7] in 50 per cent of the Cook County Hospital series reported by Koucky, Beck and Hoffman[25] in 1940 and in 88 per cent of the Massachusetts General Hospital series reported by Warren and Linton[38] in 1948.

Peripheral arterial embolization should be anticipated in all patients with history of signs of heart disease especially when there is a change in the status of the heart disease. Since small emboli may cause minor occlusions before a major vessel is blocked, premonitory signs such as a twinge of pain, a transient cramp, unexplained muscle soreness or ache, local changes in motor or sensory function of minor degree or changes in skin temperature may precede major embolic occlusion.

The onset of embolic occlusion is usually, but not always, characterized by sudden pain. The presence of pain depends upon the degree of narrowing of the major vessel, the amount of spasm caused, the state of the collateral circulation and the amount of muscle rendered ischemic. Cases have been reported in which complete occlusion of major vessels has occurred without pain (5.7 per cent in Haimovici's series). Occlusion is usually followed by the absence of pulsations and oscillometric excursions. The linear thrust of an occluded vessel due to the impact of the column of blood on the embolus is

---

*From the Department of Surgery, Stritch School of Medicine, Loyola University.

Presented at the Annual Meeting of the Duluth Surgical Society, Duluth, Minn., May 14, 1952.

called Nordentoft's sign and has frequently misled the examiner to conclude that the involved vessel was pulsating normally. The veins empty and sensory and motor paralysis soon follow. There is a drop in the skin temperature, marbling of the skin develops and muscle rigidity occurs in response to the ischemia.

The association of heart disease and peripheral emboli is so frequent that in the absence of auricular fibrillation, coronary occlusion or endocarditis, the diagnosis of pheripheral arterial embolus from a cardiac source must be made with great care.[38] One must then consider the unusual sources of emboli such as an aortic plaque, tumor embolus or paradoxical embolus. Foreign body emboli are rare. They are usually metallic and are related to recent trauma, most commonly gunfire. Accounts of their bizarre migrations are often fascinating.[23]

The differential diagnosis must include thrombophlebitis which often has a sudden onset and is accompanied by enough arterial spasm to render the peripheral pulses feeble so that their presence might be questioned. It occurs as a rule, however, under different circumstances afflicting more commonly patients already at bed rest from a medical illness or in post-partum or post-operative patients. The presence of edema, the lack of motor or sensory paralysis and the absence of demonstrable heart disease will usually suffice to make the distinction. Massive venous thrombosis may produce a picture locally in the extremity which may, for a time, closely simulate arterial occlusion.

Spontaneous thrombosis in a previously diseased and narrowed vessel may occur with such rapidity that embolization may be suspected. Consideration of the age of the patient, the absence of heart disease, the history suggesting gradually diminishing blood supply to the extremities and the physical signs associated with ischemia are the major points in the differentiation. Spontaneous thrombosis may occur in either arteriosclerotic peripheral vascular disease or in thromboangiitis obliterans. Some of the peripheral manifestations of dissecting aneurysm may suggest embolic occlusion but the mode of onset, the changing symptoms as the dissection progresses, and the late disturbance of pulse in either leg should be the basis for differentiation. A ruptured aneurysm of the abdominal aorta may interfere with pulsations in one leg. However, the associated collapse is usually more than is seen with uncomplicated embolic occlusion, and study of the peripheral blood will often suggest hemorrhage.

Very little has been written concerning embolism in infancy and childhood.[8,13] In patients with congenital heart disease sterile vegetations may form on the valves and in the cyanotic group the polycythemia is usually accompanied by increased clotting activity. A patent ductus is not considered an anomaly during the first year of life. However, clot can form in it and can break away from either end of the unobliterated channel. The clot which obliterates the umbilical arteries may extend into the iliac vessels and cause gangrene of an extremity. The diagnosis is, as a rule, difficult and usually is not made until there is obvious circulatory disturbance with marked physical signs. The treatment is conservative because the nature of the occluding mechanism is not always firmly established and because of the technical hazards of embolectomy in small vessels. The amazing capacity of the collateral circulation to provide adequate blood supply further justifies conservatism.

The management of patients in whom peripheral arterial embolism is suspected or in whom the diagnosis appears to be on a sound basis begins with a period of observation. Much can be accomplished during this time by careful evaluation of the general condition of the patient, careful consideration of the probable risk of operation and making arrangements for all the safeguards such as skillful anesthesia, capable assistants, appropriate instruments and materials, blood for transfusion and suitable provisions for the use of anticoagulant therapy. Embolectomy is an emergency procedure and from personal experience it may be said that most embolectomies will be done at odd hours when less experienced personnel are "on call." The surgeon must anticipate all of his needs prior to operation because in the final analysis he alone is held responsible for the clinical result.

In addition to allowing time for suitable preparation a period of observation will enable one to study the effect of antispasmodic treatment by drugs given systemically and by local anesthetic agents used in blocking the sympathetic pathways to the extremity. The response to antispasmodic therapy will enable one to select the cases in which operation is indicated. It will differentiate those conditions which are not embolic and it will disclose the true nature of those conditions in which a minor embolic occlusion has occurred but severe circulatory changes have been caused by superimposed vasospasm. The value of an observation period has been emphasized by Haimovici[16] and Veal and Dugan.[37] The latter authors point out that a good response to a sympathetic block should relieve pain, and restore color, temperature and function. If a good response is not obtained operation is performed. Veal and Dugan state that operation can be done before irreparable damage has occurred after a "safe period" of several hours. This seems quite reasonable since the chances of a successful embolectomy decrease rapidly after six hours.

The site of occlusion also furnishes some indication for the form of treatment; thus conservative management appears to be followed by the best results in the upper extremity. Lund[26] does not believe that operation for axillary or brachial emboli is beneficial. DeTakats[10] says it is seldom indicated, Veal and Dugan elect to treat their cases of upper extremity occlusion conservatively and Blum[5] states that embolic occlusion in the upper extremity runs a benign course. The collateral circulation about the shoulder joint is the greatest factor in maintaining adequate blood supply to the extremity but it can also be pointed out that the degree of circulatory impairment rarely is as marked in the upper extremity as it is in the lower even in the presence of generalized arterial disease. The poor results of embolectomy in the upper extremity may be related to the relatively smaller size of the vessel from which the clot is removed and the tendency for it to be narrowed by subsequent suture. Nevertheless, embolectomy in the upper extremity often stops the pain and may decrease spasm and avoid clotting by extension into the collateral vessels.

Emboli to the vessels of the lower extremity most commonly are arrested at the origin of the profundis femoris and therefore lend themselves to removal under local anesthetic by a femoral arteriotomy. If the clot is lodged in the iliac artery it may be fragmented by maneuvers with probes or by suction with a catheter introduced proximally through the opening in the vessel. The force of the blood proximal to the clot will sweep it into the section of vessel exposed. Care must be used to avoid permitting clot fragments to escape into the vessel distal to the arteriotomy. If one recalls the great tortuosity and calcification found on occasion in the iliac arteries, maneuvers to dislodge clot on these vessels by probing will be done with extreme care and caution.

In saddle embolus of the aorta the outlook without operation is so poor that embolectomy is almost universally accepted as the procedure of choice.[22] The cases in which survival has followed conservative therapy do not appear to be ones in which complete occlusion at the aortic bifurcation was present in previously normal vessels. Transitory arrest of a clot at the bifurcation followed by fragmentation or division of the clot resulting in bilateral iliac obstruction or iliac obstruction on one side and femoral on the other can be confused with saddle embolus. The prognosis in these situations is not the same since the level of gangrene is different. Collateral circulation developed in response to the gradual narrowing of the aorta in the region of the bifurcation may permit survival of an extremity following the complete and sudden occlusion of the remaining narrow lumen.

The general condition of the patient with a saddle embolus will determine the surgical approach and the anesthesia required. The abdominal approach is by far the most satisfactory and is usually made transperitoneally. This direct exposure appears to be more satisfactory for most surgeons although Murray[31] prefers an extraperitoneal route. It has a great advantage in aortic embolectomy in the presence of intraperitoneal sepsis as reported by Schmorell[33] and should be considered in patients with previous peritonitis in order to avoid extensive dissection of adhesions.

An indirect approach to an aortic embolus can be made through the femoral arteries in patients whose general condition does not justify an abdominal approach. Clot can be dislodged from the bifurcation by probing and the force of the blood stream will sweep the fragments distally to the site of the arteriotomy wound from which they can be recovered. Retroperitoneal milking as described by Nystrom has been attempted but this involves passing the hand retroperitoneally along the iliac vessels to the region of the bifurcation and then compressing the vessels while withdrawing the hand. It is difficult to see how this could be accomplished under local anesthesia.

The general principles of embolectomy are essentially the same for all vessels. There must be adequate exposure, control of bleeding from the main vessel and from the collaterals, removal of all clot as shown by adequate flow of blood when the hemostatic tapes are released and re-establishment of pulses, color, warmth and function. There is usually no problem in dislodging clot proximal to the site of embolectomy and allowing the force of the blood stream to clear the main vessel. The problem is to recover the clot which is distal in the main vessel and in the collateral channels. A variety of maneuvers have been employed to accomplish removal of clot distal to the arteriotomy wound. They include the use of probes of many types, suction by means of a catheter and flushing the vessel with solution introduced at a more distal level. The possibility of retrograde milking of the collaterals and the distal portion of the main vessel was considered in a personal case some time ago and more recently was used with success in a case of femoral embolus.[21] The milking effect of a para rubber bandage wrapped tightly from the toes upward brought additional clot to the level of the arteriotomy wound through which it was recovered. It was our opinion that the recovery of the additional clot was responsible for the successful outcome.

The postoperative management must first of all take into consideration the patient's general condition and particularly his cardiac status. Often the patient is recovering or has recovered from an episode of decompensation when the embolus occurs and the stress of embolectomy may bring about decompensation again. Since the survival of the parts concerned depends on adequate oxygen, any improvement in the function of the heart will improve whatever peripheral circulation the condition of the vessels will permit. Likewise any improvement in the oxygen carrying power of the blood will be beneficial and red cell and hemoglobin values should be restored to normal levels by transfusion, due attention being paid to the burden transfusion may place on the cardiovascular system from a volume standpoint and the risk of a possible reaction.

Vasospasm may so limit the amount of blood reaching a part as to jeopardize the outcome of an embolectomy. Repeated lumbar or cervical sympathetic blocks are certainly in order and should be used as long as they appear to be beneficial. As a rule, the outcome of the case begins to be obvious within a few days and needless sympathetic blocks can be avoided. Early in the postoperative course when anticoagulant effect is still probably due principally to heparin the sympathetic blocks can be timed to coincide with lessened anticoagulant activity to avoid hematoma formation. Continuous sympathetic block by repeated infiltration of local anesthetic solutions through an arrangement similar to that used for continuous spinal anesthesia has been used.[35]

Effective anticoagulant therapy should be used in every embolectomy. It prevents reformation of clot at the arteriotomy site and propagation of clot from unrecovered distal fragments in either the main vessel or collaterals. Heparin should be injected through a fine needle directly into the involved vessel proximal to the arteriotomy site before the parietal wound is closed. Directing the needle distally will tend to make a valvelike puncture wound in the vessel. Subsequent anticoagulant therapy of heparin and dicoumarol or tromexan is used until the depression of prothrombin activity due to the longer acting agents is sufficient. If heparin is used in the form of a continuous drip intravenously care must be used to avoid overloading the circulation by two much fluid or salt. Wound hematomas may be troublesome on occasion but are not sufficient reason for omitting anticoagulant therapy.

Physical means to increase the circulation in an extremity may be used but it is difficult to estimate their value. Certainly no harm can come from using Berger's exercises if they do not tax the strength of the patient. The experimental evidence is inconclusive concerning the value of intermittent venous occlusion in increasing the blood supply to an extremity, yet there are many who feel that there is benefit from this adjunct in therapy. Other means to dilate the vessel such as alcohol in proper dosage and reflex vasodilatation by application of heat to other parts of the body may also be employed.

Sympathectomy has been employed as a rule for residual vasospasm but bilateral sympathectomy at the time of aortic embolectomy may be of value as suggested by Albright and Leonard.[2] Leriche seems to be the most prominent proponent of arteriectomy and offers the following indications for its use: poor general condition of the patient where speed is essential, badly damaged arterial wall, late cases (after twenty-four hours), and secondary thrombus formation after embolectomy. The arteriectomy removes an irritable focus which has been described as a trigger point for spasm.

Recurrent and multiple emboli constitute a threat which fortunately is not frequently encountered. Deitch[9] in 1936 reported three embolectomies in the same patient. Groth[14] in 1939 found four of six re-embolectomies reported in the literature successful. McFarlane[28] in 1940 reported four successful embolectomies in the same patient and Scott and Williams[34] in 1949 reported three successful embolectomies in a patient with subacute bacterial endocarditis, an uncommon cause of larger peripheral emboli as a rule.

Recurrence of emboli and the constant threat of embolism in patients with fibrillation have prompted a medical and surgical prophylactic viewpoint. In 1946 Dock suggested that auricular resection be done in cases of recurrent embolization associated with rheumatic heart disease with mitral stenosis and auricular fibrillation. It has been shown experimentally in dogs.[6,17] that no disturbance followed this procedure and it has been used successfully in human beings by Madden,[29] Beal, Longmire and Leake[4] and by Baronofsky and Skinner,[3] but Leonard and Cogan[27] recently reported failure of the procedure in preventing recurrent embolization. This is readily understandable as the clots in rheumatic heart disease with mitral stenosis and fibrillation are not confined to the auricular appendage. It is too early to say whether the surgical procedure will be justified by the results and by the number of cases in which it is applicable.

The medical alternative is the restoration of normal rhythm, which may be impossible in a large majority of the patients, with the institution of prolonged anticoagulant therapy with dicoumarol or one of the newer therapeutic agents of that type.[11]

Summary

A résumé of the sources, behavior and occlusive effects of peripheral arterial emboli is presented. The problems in diagnosis, the basis for choice of treatment and technical problems in management are discussed. Adjunct therapy after embolectomy is described and the problems of recurrent embolization are presented in the light of recent thought and practice.

A HISTOPLASMIN AND TUBERCULIN STUDY OF PSYCHIATRIC PATIENTS HAVING ABNORMAL CHEST ROENTGENOGRAMS

MILLARD A. TROXELL, M.D.
Saint Paul, Minnesota

DURING the last few years histoplasmosis has assumed increasing prominence in the differential diagnosis of many diseases. Outstanding among these is tuberculosis, together with the pathologic processes ordinarily considered in the differential diagnosis of tuberculosis. Since the relationship of tuberculosis to mental illness has long been recognized, even though the mechanism and degree of relationship remains unknown, it was considered appropriate to investigate a possible relationship between histoplasmosis and mental illness. The results of this study, although inconclusive, are suggestive of such a relationship; for this reason they are considered of sufficient interest for publication.

Early studies with histoplasmin skin tests have indicated an association between histoplasmin sensitivity and pulmonary calcification in tuberculin negative individuals.[4] More recent work has shown that pulmonary infiltrations resembling tuberculous infiltrations occur in these histoplasmin-positive, tuberculin-negative individuals.[5,7] Hilar lymphadenopathy was observed in histoplasmin positive, tuberculin negative infants but the infants had not been followed long enough to determine whether these lesions went on to calcification.[2] Two-thirds of seventy-two asymptomatic Kansas City school children showed nodular, sharply circumscribed foci, one-quarter showed diffuse patchy infiltrations, a few were limited to the lymph node, and a few were disseminated.[7] Cases of infected pulmonary cysts were pathologically diagnosed as histoplasmosis after lobotomy.[9] Schwartz and Spitz[20] mention the non-characteristic roentgenogram in the acute state of histoplasmosis but advise giving the diagnosis serious consideration in the presence of a disseminated pneumonitis. They explain cases showing complete resolution of the infiltrations as having been caused by relatively small doses of the infecting organism; the more intense inflammations supposedly result from greater doses of the infecting organism and take longer to heal, with resultant fibrosis and calcification. The calcification may be confined to the center of the lesion, producing a halo effect. Miliary and somewhat larger calcified nodules scattered diffusely throughout the lung fields strongly suggest the end stage of pulmonary histoplasmosis.[20]

Calcification was two to four times as frequent in histoplasmin positive University of Wisconsin students as in the tuberculin positive.[5] Iams[10] reviewed histoplasmin and tuberculin tests reported prior to his paper and summarized the relation of the tests to pulmonary calcification as follows: 13 per cent were histoplasmin and tuberculin positive; 69.5 per cent were histoplasmin positive and tuberculin negative; 5.3 per cent were histoplasmin negative and tuberculin positive; 12.1 per cent were histoplasmin and tuberculin negative. He quotes J. W. Johnson in a personal communication as finding 8 per cent positive reactors in five hundred tests done in Minneapolis. J. A. Myers of the School of Public Health at the University of Minnesota Medical School, informs me that histoplasmin tests have been routine on new students entering the University of Minnesota since 1947 and that an estimated 10 per cent are reactors. "Usually these students are from areas well to the south of us.[13]

However, in examining a study in student nurses[16] with particular regard to Minneapolis, 4.2 per cent of 2,419 were histoplasmin positive—3.6 per cent of these being tuberculin negative and 0.6 per cent tuberculin positive; 95.8 per cent were histoplasmin negative (a doubtful test is considered negative), 88.5 per cent being tuberculin negative and 7.3 per cent being tuberculin positive. Only sixty-three of the 2,419 had pulmonary calcification, with twenty-eight or 1.1 per cent having positive histoplasmin tests and thirty-one or 1.3 per cent having positive tuberculin tests. If the nine cases which were both histoplasmin and tuberculin positive are omitted, histoplasmosis *could* be suggested as the cause of the calcification in the nineteen (0.8 per cent) histoplasmin

---

A. L. Reichenberg, M.S., gave technical assistance in this study, which was performed in the Division of Research and Training, Hastings State Hospital, Hastings, Minnesota, Ralph Rossen, M.D., Superintendent.

Dr. Troxell is a medical fellow, the University of Minnesota, Division of Dermatology, H. E. Michelson, M.D., Director.

positive and tuberculin negative, and tuberculosis as the cause in the twenty-two (0.9 per cent) histoplasmin negative and tuberculin positive cases. This would seem to suggest tuberculosis and histoplasmosis as equally important causes of pulmonary calcification in this area.*

Other agents must not be ignored as causes of pulmonary calcification. Most non-tuberculous anergic patients usually have no symptoms at all in spite of roentgenograms that look alarming, and these patients are discharged from the sanatorium with the diagnosis of sarcoid disease, bronchiectasis, atypical pneumonia, tracheobronchial lymphadenitis, or one of the fungus infections.[23]

Nevertheless, the cause of abnormal chest roentgenograms should be established if possible, and the study herewith reported was undertaken with this in mind.

Procedure

Exclusive of the receiving wards, the average patient population of the Hastings State Hospital is 900. Of these, 103 had abnormal chest roentgenographic findings. All patients tested had been under consideration as suspected cases of tuberculosis, on the basis of miniature film reports from the Minnesota State Health Department Division of Tuberculosis mass survey, and also from reports of chest films taken here. Repeated gastric lavages on these patients were negative except in the case of one histoplasmin negative and tuberculin positive patient discovered after the testing was done. He was immediately transferred, since no proven case of tuberculosis is allowed to remain at this institution.

For convenience the patients were tested in three working groups, the basis of selection being their ward of residence at the institution. Three different shipments of histoplasmin were used.** Three different shipments of tuberculin diluted 1:1000 were obtained from the Minnesota State Department of Health. In all cases the test material was used within two weeks of receipt. An amount of 0.1 cc. was injected intradermally into the volar forearm; in most cases the tests were done at the same time—the left forearm being tested with histoplasmin and the right with tuberculin. Immediately after skin testing, blood was drawn for complement fixation testing and was airmail shipped the same day. The author did all the skin testing and interpreting. The tests were interpreted forty-eight hours after testing by measuring two perpendicular diameters and recording the erythema, edema, and necrosis, if any. Then the degree of positivity was later calculated from the larger diameter according to accepted Minnesota Health Department standards for tuberculin test interpretation:

1 plus reaction—slight but definite edema not more than 10 mm. raised about 1 mm.
2 plus reaction—well defined edema 10-15 mm. in diameter raised somewhat more than 1 mm.
3 plus reaction—extensive edema more than 15 mm. in diameter and raised more than 2 mm. There might be some redness along a lymphatic, but no necrosis.
4 plus reaction—extensive edema, redness, and a spot of necrosis.

In accordance with well established precedent, a positive reaction to histoplasmin was not diagnosed unless the edema measured 5 mm. or over. Readings from the first working group were taken at forty-eight and also seventy-two hours, but no difference in the test readings was noted in those thirty patients. Consequently, tests were read only at forty-eight hours in the other two working groups.

Results

Of the 103 patients tested, ninety-five were tuberculin positive and forty were histoplasmin positive. For analysis (Table I) the patients were divided into two groups: (1) histoplasmin positive, and (2) histoplasmin negative, to see if there were any essential difference in the two groups. Complement fixation tests for histoplasmosis were done at the Federal Security Agency Communicable Disease Center in Chamblee, Georgia, on sera drawn from all patients skin tested, and results were entirely negative. Complement fixation tests for blastomycosis and coccidioidomycosis were also done on sera from the first working group of thirty patients, and these were also completely negative.

For comparison, the roentgenographic findings of the seven patients who were tuberculin and histoplasmin negative are given: Four (57.2 per cent) showed apical densities; two (28.5 per cent) showed apical fibrosis; and one (14.3 per cent) showed basal densities. The one patient who had a histoplasmin positive and a tuberculin negative reaction showed apical fibrosis with no calcification.

---

*The Hastings State Hospital is approximately twenty-five miles southeast of the Twin Cities.

**Supplied on request by Dr. M. L. Furcolow.

I would have preferred to find more histoplasmin positive, tuberculin negative patients, but this was not to be. In a way this is an advantage because nearly all (92 per cent) of the patients tested were tuberculin positive, and thus the patients could be divided into histoplasmin positive and histoplasmin negative groups with the factor of tuberculin sensitivity held constant, as it were.

The test results can be summarized as follows (Table I):

1. The average age and length of hospitalization of the two groups were nearly identical.

2. There was little difference in the psychiatric diagnoses, with the exception of a greater incidence of histoplasmin sensitivity in the paretics and a greater incidence of histoplasmin negativity in the manic depressives. No significance is attached to these findings.

3. Of the forty positive histoplasmin tests only one (2.5 per cent) was four plus, and only two (5.0 per cent) were three plus.

4. The incidence of apical densities in the histoplasmin positive group was only half that of the histoplasmin negative group. On the other hand, the incidence of apical fibrosis in the histoplasmin positive group was over twice that of the histoplasmin negative group. The histoplasmin positive group showed twice the incidence of pulmonary calcifications as compared to the histoplasmin negative group. However, six of the seven "anergic" patients showed apical densities or fibrosis.

5. There was a greater incidence of four plus tuberculin reactions in the patients who reacted to histoplasmin than in the patients who did not.

6. The tuberculin skin test showed a more intense reaction in thirty-four (85 per cent) of the patients who reacted to both test materials.

TABLE I.

	Histoplasmin positive		Histoplasmin negative	
Number of patients	40		63	
Average age	62 years		61 years	
Average length of hospitalization	24 years		23 years	
Psychiatric Diagnosis				
Schizophrenia	24	60.0%	35	55.5%
Manic-Depressive	3	7.5%	11	17.4%
Psychosis with Psychopathic Personality	2	5.0%	1	1.6%
Senile Psychosis	4	10.0%	6	9.5%
Paresis	4	10.0%	2	3.2%
Involutional Melancholia	2	5.0%	0	0.0%
Organic Psychosis	0	0.0%	2	3.2%
Psychosis with Mental Deficiency	0	0.0%	3	4.8%
Alcoholic Psychosis	0	0.0%	1	1.6%
Undiagnosed	1	2.5%	2	3.2%
Main Roentgoenographic Finding				
Apical densities	9	22.5%	28	44.5%
Nodular	2	5.0%	3	4.8%
Mottled	1	2.5%	1	1.6%
Soft	1	2.5%	1	1.6%
Not specified	5	12.5%	23	36.5%
Apical fibrosis	19	47.5%	13	20.6%
Without calcification	12	30.0%	12	19.0%
With calcification	7	17.5%	1	1.6%
Apical infiltration	2	5.0%	1	1.6%
Pleural thickening	5	12.5%	3	4.8%
Hilar calcification	2	5.0%	7	11.1%
Basal densities	3	7.5%	11	17.4%
Calcification (Apical and Hilar)	9	22.5%	8	12.7%
Reaction of Tuberculin Tests				
4 plus	20	50.0%	20	31.8%
3 plus	12	30.0%	18	28.6%
2 plus	6	15.0%	14	22.2%
1 plus	1	2.5%	4	6.3%
Negative	1	2.5%	7	11.1%
Reaction of Histoplasmin Tests				
4 plus	1	2.5%		
3 plus	2	5.0%		
2 plus	10	25.0%		
1 plus	27	67.5%		
Comparison of Tuberculin and Histoplasmin Reactions				
Tuberculin more than Histoplasmin	34	85.0%		
Tuberculin equal to Histoplasmin	3	7.5%		
Tuberculin less than Histoplasmin	2	5.0%		
Tuberculin negative; Histoplasmin 1 plus	1	2.5%		

7. Histoplasmin complement fixation tests on all 103 patients were negative.

Discussion

No reference to a numerical gradation of the histoplasmin test was found in the literature reviewed. A complicated system using capital letters of the alphabet has been used.[16] However, Keeney,[11] states that the histoplasmin skin test is performed by injecting 0.1 cc. of a 1:1000 dilution of Histoplasma capsulatum broth filtrate and is interpreted in the same manner as the tuberculin test. Hence, grading histoplasmin tests into one, two, three, and four plus seems logical.

It is extremely difficult to evaluate the mass of histoplasmin tests reported in the literature. Many different lots and dilutions of histoplasmin have been used. The reader is referred to an article by Shaw et al[21] for further information.

Considerable doubt has been raised regarding the usefulness of the histoplasmin test. Olson, Bell and Emmons[15] state that the histoplasmin skin test is not specific for histoplasmosis in animals and no evidence has been found that the reaction is specific for histoplasmosis in humans. These conclusions are based on histoplasmin tests in guinea pigs, rabbits and man. Prior et al[17] state "in the many thousands of histoplasmin tests applied to man in this country very few have actually detected histoplasmosis. For this reason many doubt the diagnostic value of the histoplasmin skin test." They regard the test in dogs in a more favorable light, however, since only five of 837 tested were positive and three of the five were proved to have active, naturally occurring histoplasmosis. All three had failed to react to tuberculin. Emmons et al[6] reported positive histoplasmin reactions in animals experimentally infected with blastomycosis, coccidioidomycosis and haplosporangiosis, but Christie and Peterson[3] concluded that the cross reactions noted by Emmons are not seen in humans. Saslaw and Prior[18] conservatively note that a positive skin test may serve to include the disease in the differential diagnosis but there may be no skin reaction in fulminating or disseminated disease. This seems a sensible interpretation of the problem.

The complement fixation test does not seem to be much greater help in attempting to find the cause of persistent pulmonary infiltrations and calcifications. Complement fixation and collodion agglutination tests are usually of value in the early acute phase of the disease.[18] Saslaw and Campbell[19] found strong agglutination between histoplasmin sensitized collodion particles and sera from all of three patients in the acute phase of histoplasmosis but the titre of the serum was appreciably decreased after two months of the disease and three chronic cases showed a lack of significant circulating antibodies. According to the authors there was implicated a transient type of antibody response to Histoplasma capsulatum following infection. The same authors,[1] using ground yeast phase antigens of Histoplasma capsulatum, found that sera from three acute cases fixed complement in high titre while sera from three chronic cases did not vary appreciably from titres found in a small percentage (viz. 5.9 to 7.7 per cent) of a normal population. However, Furcolow, Bunnell, and Tenenberg[8] used histoplasmin as antigen and found that the fourteen positive complement fixation tests among 300 human sera tested all belonged in a small group of fifty-eight persons. Nine of these were definitely proved cases, thirteen had recently acquired histoplasmin skin sensitivity, and thirty-six had unhealed lung lesions "characteristic of those associated with histoplasmin skin sensitivity."

The tuberculin test also deserves discussion. The 1:10,000 dilution has been widely used. Since the 1:1,000 dilution is in common use, it would seem that the use of the weaker preparation would merely increase the number of tuberculin negative patients. If these patients tested histoplasmin positive, erroneous conclusions could be reached. Indeed—Woodruff[23] mentions that in 1,376 patients admitted to a sanatorium because of roentgenographic or other findings suggestive of tuberculosis—1,302 or 94.7 per cent reacted to 1:1,000, 1:10,000, or 1:100,000 dilutions of tuberculin, and 1,125 or 86.4 per cent reacted to 1:10,000 or 1:100,000 dilutions. Hence 8.3 per cent more patients were tuberculin positive when tested with the 1:1,000 dilution. On the other hand, only 5 per cent of the patients were "anergic"—either because they were critically ill with tuberculosis or because they did not have tuberculosis at all. Woodruff would have obtained over two and one-half times the number of tuberculin negative patients by testing only with tuberculin diluted 1:10,000 or 1:100,000. I have come to believe that many of the "histoplasmin positive, tuberculin negative" patients reported as such are not truly tuberculin negative, and use Woodruff's statistics to add weight to this statement. Furthermore, Weissfeiler[22] concludes that tuberculous infection is accompanied by an increased sensitivity to non-specific antigens as well as to various components of the tuberculosis bacillus. This mechanism *could* account for some of the histoplasmin positives.

The relationship between tuberculosis and mental illness has been long recognized. Fifty-three references on this relationship were mentioned in the publication by Nolan Lewis,[12] and these references include only the years 1922 to 1935! Oechsli[14] mentions a higher incidence (7.5 per cent) of tuberculosis in patients with dementia praecox as compared to the incidence of tuberculosis (4.8 per cent) in patients with other psychiatric diagnoses in California mental institutions. He ascribes this to the longer periods of residence of patients with dementia praecox, with consequent greater opportunity to acquire tuberculosis. In contrast, the incidence in recently admitted patients was 1.6 per cent, or about the incidence observed in the California general population.

Because of the difficulties in distinguishing findings due to histoplasmosis and tuberculosis on pulmonary roentgenograms, and with the widespread distribution of histoplasmosis now being reported, a similar increased incidence of histoplasmosis could be expected in mental institutions. It was not possible to test all 900 patients at Hastings State Hospital, but forty reactors in the 103 patients tested (38.9 per cent) is a vastly greater incidence over that previously found in this area.

Conclusions

1. Neither the histoplasmin skin test nor the histoplasmosis complement fixation test has helped establish the cause of "suspicious" pulmonary roentgenograms in the 10 per cent of our patients who have them.
2. Caution is recommended in assuming patients to be tuberculin negative unless they are tested with the 1:1,000 dilution of tuberculin.
3. There may be an increased incidence of histoplasmin reactors among patients at state mental institutions. Thirty-nine per cent of patients tested were positive, as opposed to incidences of 4 to 10 per cent previously found in this immediate area.

NEUROSYPHILIS

ROBERT R. KIERLAND, M.D.
Rochester, Minnesota

TREMENDOUS advances have taken place in syphilotherapy in the past twenty years. These range from the seemingly endless courses of arsenicals, bismuth, mercury, iodides with or without fever in the form of malarial therapy, Kettering hyperthermy, typhoid vaccine, hot baths and blankets, and even other supplemental types of treatment such as Swift-Ellis therapy or one of its modifications, to the present-day therapy with penicillin.

In spite of the great simplicity and efficacy of therapy with penicillin, and in spite of the great reduction in the number of patients with all forms of syphilis, the patient himself remains the same and has the same signs and symptoms that he would have had if he had been seen twenty or thirty years ago.

The diagnosis of neurosyphilis, of course, depends on the history, complete physical examination, including a neurologic examination, and on confirmation by a serologic test for syphilis and examination of the cerebrospinal fluid. The exception to this may be seen in cases of arrested locomotor ataxia in which the results of a serologic test for syphilis and examination of the cerebrospinal fluid may be normal, but in such cases thorough neurologic examination will point out the diagnosis. Thorough examination is necessary because patients who have been thought to have arrested locomotor ataxia later have been found to have Adie's syndrome or pseudotabes of diabetes.

In the short time available for this presentation, it is impossible to speak of neurologic examination further or to discuss the classification of neurosyphilis extensively.

There is almost no limit to the many manifestations that may be due to neurosyphilis. The pathologic changes are both inflammatory and degenerative, and the type of neurosyphilis encountered depends upon which change is present, whether or not there are combinations of both, and the site of involvement within the central nervous system.

The Co-operative Clinic Group a number of years ago classified neurosyphilis, and the following classification is a minor modification of the one by this group.

I. Asymptomatic neurosyphilis.
II. Acute meningeal neurosyphilis.
III. Meningovascular neurosyphilis.
IV. Vascular neurosyphilis.
V. Locomotor ataxia (tabes dorsalis) with or without optic atrophy.
VI. Dementia paralytica (general paresis).
VII. Taboparesis.
VIII. Rare types of neurosyphilis.
  A. Gumma of brain or spinal cord.
  B. Syphilitic epilepsy without paresis.
  C. Erb's spastic paraplegia.
  D. Eighth-nerve deafness.
  E. Primary optic atrophy.

The absolute certainty that a few of these conditions are due to syphilis is sometimes remote in any individual case and may depend upon a therapeutic trial or even necropsy, for, in certain cases, that is, in cases of vascular neurosyphilis, epilepsy, gumma of brain or spinal cord, eighth-nerve deafness or optic atrophy without locomotor ataxia, the cerebrospinal fluid may be normal. Nevertheless, the diagnosis of active neurosyphilis usually cannot be made without the demonstration of abnormal changes in the cerebrospinal fluid. The previously mentioned exceptions should be noted. These abnormal changes in the cerebrospinal fluid in order of importance are: (1) increased cell count, (2) increased concentration of protein, (3) positive serologic reaction for syphilis and (4) abnormal result of the colloidal gold test.

The cell count is usually the first abnormality seen and is the finding of greatest value in determining response to treatment, for the trend toward normal appears rapidly. The opinions of laboratory workers and syphilologists differ as to what the upper limit of normal is. It usually is

---

Read at the meeting of the American Academy of Dermatology and Syphilology, Chicago, Illinois, December 6-11, 1952.

considered to be between five and seven lymphocytes per cubic millimeter without any polymorphonuclear leukocytes.

The values for protein again vary slightly from laboratory to laboratory, but values up to 35 to 40 mg. per 100 cc. may be considered normal. The values for protein are increased early in cases of active neurosyphilis, and after treatment is started they usually begin to revert to normal shortly after the cell count does. Occasionally, and without known reason, the values for protein may remain elevated for a long time, even when other tests show a steady significant trend or even a return to normal.

The positive result of a serologic test for syphilis, which preferably should be a complement-fixation test, which is confirmatory of a diagnosis of neurosyphilis, occasionally may be the first abnormality found in the cerebrospinal fluid although such a positive reaction usually follows abnormalities of the cell count and values for protein. After treatment, the quantitative complement-fixation reaction usually decreases in titer but only becomes negative months or even years after the values for the protein and cell count have reverted to normal, even in cases in which the response to treatment is favorable.

The result of the colloidal test, which now in most laboratories is known as the "colloidal gold test," also exhibits abnormalities, but the type of reaction does not always indicate the type of neurosyphilis encountered clinically. The result of this test, like the result of the complement-fixation reaction, very slowly reverts to normal after treatment is started. Peculiarly, in cases in which patients were treated with aureomycin at the Mayo Clinic, which I shall mention later, the result of the colloidal gold test exhibited a far more rapid reversion to normal than in cases in which patients were treated by penicillin or other methods.

The response of these tests to treatment has been the subject of interest and investigation by syphilologists for many years, and from these investigations has come the frequently called Dattner-Thomas concept which states that the results of cerebrospinal-fluid tests accurately reflect the activity of a syphilitic process in the central nervous system. This concept of cerebrospinal-fluid findings in cases of neurosyphilis has been summarized as follows by Thomas:

"1. Signs and symptoms of neurosyphilis are not reliable criteria of the activity of a syphilitic process in the central nervous system, because they may persist or become more marked as a result of past activity, or there may be transitory clinical improvement without a complete arrest of the syphilitic process as shown by spinal fluid findings. Also, the syphilitic infection may be very active within the central nervous system and still be asymptomatic.

"2. A positive spinal-fluid Wassermann test alone is not proof of active neurosyphilis. It merely indicates the specific nature of the infection, which may be already inhibited or completely checked at the time when the spinal fluid is examined. Activity is demonstrated only by the entire spectrum of spinal-fluid tests, among which increased cell counts and total protein determinations are of chief importance. Colloidal reactions are important but less informative than cell counts and protein determinations.

"3. In treated cases, spinal-fluid Wassermann tests and colloidal reactions may continue positive for more than five years after treatment has successfully arrested the syphilitic process. In an arrested case, cell counts should become normal within three to four months after treatment, and quantitative complement-fixation tests, protein values, and colloidal reactions should show a gradual but steady trend toward normal.

"4. Following malaria therapy or penicillin therapy of active neurosyphilis, the spinal-fluid findings may show a trend toward normal values, only to relapse later. Relapses however, rarely occur more than one year after therapy, and at Bellevue Hospital we have never observed a relapse of neurosyphilis more than fifteen months after treatment. If the cell count is not normal and there is no definite improvement in the other spinal-fluid findings six months after treatment, further treatment is imperative, regardless of the clinical status of the patient."

Few rules for the treatment of syphilis are without exception, and at the clinic we have seen but few exceptions to those which have been mentioned. We, therefore, feel, as do most investigators, that the concept of Thomas is valid. Since we have seen cell counts which were abnormal six months or more following treatment become normal without further treatment, we do not feel necessarily that further treatment is imperative, and we also have seen neurosyphilis relapse more than fifteen months after treatment with penicillin or malaria, or both.

The treatment of active neurosyphilis is now relatively simple, inexpensive and nontoxic. It consists almost without exception of the administration of penicillin. A few years ago, many of us thought that penicillin combined with malarial therapy was the treatment of choice, but it now appears that penicillin alone will accomplish as much. There are many schedules for the administration of penicillin. However, most authors[2] believe that a total dose of at least 6,000,000 units given over a period of at least ten days is adequate therapy at least for a first course. There are many variations of this schedule, for example, 600,000 units of penicillin may be administered daily for ten days, 300,000 units may be administered daily for twenty days, or 600,000 units of penicillin with 2 per cent aluminum monostearate may be administered daily, every other day, twice a week, or even less frequently.

If a test for syphilis is performed on the serum, the result of the test is of no value in determining the response of a neurosyphilitic patient to therapy. As indicated previously, the cerebrospinal fluid should be examined four to six months after the completion of the course of treatment. If the increased cell count has reverted to normal or nearly normal, if the value for the protein has decreased, and if the patient shows evidence of improvement, further treatment is not necessary. At the end of four to six months, the result of the complement-fixation reaction usually is less strongly positive than it was previously, and there may be only a slight change in the result of the colloidal gold test. Although there may be little change in the results of these tests at this time, further treatment may not be necessary. If, however, the cell count and the value for the protein remain high, the patient should receive another course of treatment with penicillin. This course should be the same as, or more intensive than the previous one.

In cases in which the response is favorable, the cerebrospinal fluid should be examined at intervals of four to six months during the first year after treatment, and then yearly until examination of the cerebrospinal fluid no longer discloses any abnormality.

It should be noted that absence of clinical evidence of improvement does not indicate that treatment has been ineffective. Irreparable injury of the nervous system may have taken place before treatment was instituted. Hence, the presence of subjective and objective signs may continue in spite of the fact that active syphilis no longer exists. On the other hand, there may be considerable clinical improvement in spite of a continuing active syphilitic process. This explains the necessity for repeated examination and continued observation of neurosyphilitic patients.

Fortunately, a patient only rarely needs further treatment after he has received two courses of treatment with penicillin. If further treatment is necessary, one should consider the advisability of using fever therapy, especially malarial therapy, or of administering one of the other antibiotics such as aureomycin.

In certain cases in which the patients are highly susceptible to penicillin, serum sickness, urticaria, eczematous eruptions and even exfoliative dermatitis may develop. In cases in which the history reveals that patients are highly susceptible to the administration of penicillin, and in cases in which its administration is followed by a reaction, one of the hypoallergenic preparations of penicillin may be used or one of the other antibiotics may be administered orally.

At the clinic, we have treated a considerable number of neurosyphilitic patients by administering aureomycin orally, and they have responded satisfactorily and to the same degree as other patients who have been treated with penicillin.[12] Other antibiotics such as terramycin and chloramphenicol also have merit, although chloramphenicol has been shown to produce hematopoietic suppression.

We have been able to continue observation on all but two of the patients who were given aureomycin and on whom we reported results previously.[9] In all of these cases, there has been a continued and rapid improvement in the condition of the cerebrospinal fluid. In one case in which a relapse occurred a second course of treatment with aureomycin produced satisfactory progress.

Clinical improvement noted early after treatment with aureomycin has continued although less rapidly. The greatest degree of clinical benefit appeared within the first six to ten months after treatment was begun. In no case of asymptomatic neurosyphilis has symptomatic neurosyphilis developed. All patients with symptomatic neurosyphilis with but one exception have shown moderate to marked degrees of clinical benefit in their specific syphilitic symptoms. In addition, there have been the general tonic effects noted as well in penicillin-treated patients; that of gain of weight and an increased sense of well-being.

While the dosage of aureomycin has varied considerably, it appears that approximately 60 gm. of aureomycin, with 2 to 4 gm. given daily in divided doses, is sufficient for a single or first course of therapy.

In cases in which the administration of aureomycin caused nausea, anorexia, and other gastrointestinal symptoms, a reduction of the daily dose often permitted continuation of the medication with comfort. Photosensitivity occurred in two cases.

From these further observations, we have concluded: (1) that results of aureomycin therapy of neurosyphilis are equivalent to those achieved with penicillin, and (2) that aureomycin is available for those cases of neurosyphilis in which the patients are hypersensitive to penicillin or the disease is resistant to this antibiotic.

Although a partial answer to the fundamental question, "What does the treatment of neurosyphilis accomplish?" is contained in much of the foregoing, this question cannot be answered completely. It seems safe to say that present-day methods of therapy of asymptomatic neurosyphilis will almost completely prevent the development of symptomatic neurosyphilis. In this respect, results may be considered almost 100 per cent satisfactory. Hence, the imperative need for the prompt suspicion and evaluation of any type of neurosyphilis.

The results of treatment of symptomatic neurosyphilis and the prognosis of the patient with this disease cannot be foretold in any individual case. These depend on the type of neurosyphilis present, the results of examination of the cerebrospinal fluid, and above all, on the amount of irreversible organic damage produced before antisyphilitic therapy is begun.

Dattner and associates[4,5] reported the results of treatment with penicillin in 388 cases of neurosyphilis. Only three of the 388 patients failed to exhibit evidence of improvement after they had received repeated courses of treatment with penicillin. Peculiarly, all of these three patients had asymptomatic neurosyphilis. In cases in which repeated courses of treatment with penicillin fail to produce evidence of improvement, another antibiotic should be administered or fever therapy should be employed.

Administration of penicillin alone or in conjunction with malarial therapy failed to produce clinical evidence of improvement in only twenty-two (6 per cent) of 380 cases reported by Curtis, Kruse and Norton. These authors said that patients who have neurosyphilis including paresis respond equally well to the administration of penicillin alone or in conjunction with malarial therapy. This opinion agrees with that of several other authors.[7,10,11] Controversy still exists, however, regarding the relative merits of penicillin when administered alone and in conjunction with fever therapy. Epstein and Allen expressed the opinion that its administration in conjunction with fever therapy produces better results.

Johnwick has demonstrated that the results obtained by the administration of mapharsen (oxyphenarsine hydrochloride) and bismuth subsalicylate in combination are no better than the results obtained by the administration of penicillin alone.

Persons who are particularly interested in this subject should read the detailed review by Beerman, Ford, Nicholas, and Katzenstein.

Conclusions

Although the results of treatment of symptomatic neurosyphilis cannot be stated dogmatically, the following conclusions appear to be warranted:

1. Administration of penicillin is the treatment of choice.

2. Fever therapy may be administered in conjunction with penicillin in certain cases, particularly in cases in which optic atrophy or severe paresis is present.

3. Other antibiotics may be used in unusual cases in which the disease does not respond to the administration of penicillin.

4. The present method of treating neurosyphilis with antibiotics is cheaper, safer, more rapid, less toxic and more effective than the older methods.

PUBLIC HEALTH SERVICE IN MINNESOTA

CHARLES G. SHEPPARD, M.D.
Hutchinson, Minnesota

FIRST of all, I should like to welcome all of you who are here tonight at our sixth annual meeting. I am sure that all of you who attended this afternoon's session, on care of the aged, have benefited greatly. The problems that lie before us in this and other public health fields are extremely challenging, and deserve our best efforts.

Secondly, I should like to take this opportunity to thank all those members of the various committees of the conference for their efforts during this past year. The growth of our organization has been slow but steady, indicating that the foundation is on firm ground. Our programs have been sufficiently varied and timely to attract the interest of those engaged in public health work, should they take the time to study the program and attend the sessions offered them. I am encouraged by the entrance into our conference of people in so many allied fields of public health work.

Last year's president, Dr. Viktor Wilson of Rochester, Minnesota, put the question, "Where do we go from here in relation to public health in Minnesota?" Dr. Wilson very fully reviewed the situation as it exists in Minnesota at the present time, and gave special emphasis to the full time public health services in Minnesota as they now are, and as he would like to see them expand in the future.

It is recognized that public health services in Minnesota are not adequate. A partial correction has been offered by an enabling act which will allow the levying of a tax to provide for local public health services in city-county, or multi-county units. The amount provided for under this law is not sufficient to provide the services that we would like to see developed.

What are some of the things that can be done to improve public health service? Bring about a change in the law to allow for more adequate financing by governmental agencies that desire such public health units to be developed. Create a greater interest in public health problems in Minnesota. This must be done by constant education of the public to the point where they are willing to expend funds for this purpose.

Who are those who are doing the educating at the present time? Public health nurses, doctors who serve as full or part time health officers, dentists, veterinarians, and groups of interested lay people. Public health activities are better directed in any community by someone who has a knowledge of public health. A great deal could be done by an interested health officer. Many of our health officers are not interested as is attested to by the fact that so few of them attend these Minnesota Public Health Conferences, either to learn or to contribute something in the promotion of better community health.

Doctors must be community leaders and each group of physicians in a community should be given the opportunity of suggesting to their city council the name of one of their group who expresses the greatest interest in public health matters as the one they would like to see as health officer. This individual should then be reappointed in this capacity year after year as long as he desires to do the work, and as long as his job is done well.

There are a great many communities that have only one doctor in the community and of necessity he must be the medical health officer. If the doctor does not happen to have an interest in public health matters, the community will suffer accordingly.

In Minnesota there are 137 communities with one doctor only. If the community is fortunate enough to have that man interested in public health, his services will be relatively good even on a part time basis. If he has no interest in public health nothing will be done. There are eighty communities where there are two doctors, and the chances are that one of them will have a greater interest in public health than the other and thus should be allowed to be the health officer as long as he will serve. There are 158 communities of three or more doctors, and there again the suggestion would be in order to let the doctors select their own health officer from their own group and let him serve year after year, to more

---

Presidential address before the Minnesota Public Health Conference, Saint Paul, Minnesota, October 2, 1952.

adequately assure continually improving public health services.

Many communities to my knowledge rotate the health officer position amongst all the physicians in that community, having each man hold office for a year. He may have no interest in the work and do nothing, or a great deal of interest and have insufficient tenure of office to accomplish improvements that he may plan. One cannot do a great deal in a one year term as a part time health officer, as I know from personal experience with these problems.

It will be years before the public is educated to the point of demanding local health units, as outlined by Dr. Haven Emerson. This is the ultimate goal, but in the meantime something else must be done.

I propose that this conference, working with such organizations as the Minnesota League of Municipalities and the Minnesota State Medical Association, promote the idea to city and village governing bodies of more careful selection of health officers and longer tenure of office as a step toward improvement of community health.

There would be much greater education in public health in each community and consequently a demonstration of the need for more adequate public health services. I would also like to suggest to the new president of the public health conference that a legislative committee be appointed to try to bring about the necessary change in the permissive legislation which was passed two years ago to establish local full time health units in Minnesota. I think if this committee could work in conjunction with a similar committee in the Minnesota Medical Association such change might be brought about in this coming legislature. This would logically be a part of the work of the already appointed committee on local public health services.

I should like to suggest the appointment of a committee of health officers to work with the executive officers of the League of Municipalities in order to try to bring about such a change in the method of appointing health officers in our communities.

I should also like to report briefly on the recent hearing held in Minneapolis, in the auditorium of the North American Life and Casualty Company. This was a hearing on the Health Needs of the Nation conducted by two members of a commission appointed by President Truman. Members of this commission who were present at the hearing were Miss Marian Sheahan of New York, and Dr. Dean Clark, of Boston, Mass. Some of you were present at this hearing, and testified for your particular group. I do not know what your impressions of this hearing were, but I should like to give you my own. I question the need of having such a commission, and the commission was given much too short a time in which to perform its function.

The commission members gave each group too little time in which to prepare a statement which would adequately tell of health needs in the various states in this section, to say nothing of time to develop suggestions for improvements in the health of our people. Each individual who testified for his organization was given exactly ten minutes in which to speak, and there were altogether too many who testified in that one day to be very constructive. A great many groups were represented at this meeting. There were spokesmen for certain farm organizations, certain labor unions, co-operative health organizations as well as the various professions associated with the practice of medicine. Representatives of many large groups, such as the Farm Bureau, refused to testify, feeling that the necessary information was already available.

Most of these groups were given exactly eight to ten days in which to prepare a statement to be given at this hearing. Certainly on a subject as important and with as many ramifications as the Health Needs of the Nation, ten days was a very inadequate period of time to come up with anything really constructive in the way of suggested improvements to say nothing of a mere description of what our health needs actually are. I think, too, that the hearing came at a most unfortunate time, that is, during a political campaign. My own impression was that not too much in the way of constructive suggestions were made, and that the possible lack of such constructive suggestions might be used politically to the disadvantage of those engaged in dealing in public health services in the country. I believe that because of the inadequacy of the testimony it will be pointed out that nobody is doing anything about real public health improvements in this country with the idea of promoting the socialization of medicine. In other words these hearings will show to those who are conducting them that there is a great need for expansion of the federal hand into health affairs in this country, because it may be pointed out that we have made few constructive suggestions as to how to solve these problems. It is definitely my feeling that if this commission had been given more time and the hearing had been conducted in a different manner and at a different time that something other than more ammunition for the socializers might have come out of it. The known socialist ideals of some of those conducting the hearings probably means that their conclusions were drawn before the hearings were held.

I believe with Dr. Roger Kennedy, president of the Minnesota State Medical Association, who said at his appearance before the sectional meeting of The President's Commission on Health Needs of the Nation held in Minneapolis in September:

> "There is really no situation existing in the health of the nation today that warrants this type of survey—especially one which is conceived in such a rapid and haphazard manner, and through which one cannot possibly hope to acquire an accurate picture of possible existing health needs, meager as they have been proved to be."
>
> "We believe that the health needs of the nation are not overwhelming, that they are being solved by the continued efforts of men of medicine and related fields who are free to practice and work without interference and control, that future problems in this field will be solved most completely and most satisfactorily through medical practice which remains free to continue its earnest quest for even better health for all people."

I believe that it behooves any organization which deals with private or public health to do its utmost to prevent the inroads of federal controls upon the health of our people, and accordingly have presented a resolution which was passed at this afternoon's business session. I sincerely hope that this organization, and all others like it in this country, will continue to oppose the ever increasing socialistic trend in our time, to the end that we here in Minnesota as in all other states, may study our own health needs and solve our own problems. There have been times where federal assistance and advice were necessary, and this will undoubtedly continue, but let us use our own ingenuity and resources whenever possible in an effort to stem the mounting tide of federal paternalism.

MANAGEMENT OF PATIENTS WITH TRAUMA OF THE CHEST

NATHAN K. JENSEN, M.D.

Minneapolis, Minnesota

PHYSIOLOGICAL considerations have led to the division of chest injuries into penetrating and non-penetrating, depending upon whether the parietal pleura has been disrupted by an object traversing the full thickness of the chest wall. Penetrating wounds are further subdivided into open and closed types. Open penetrating wounds result in a vicarious airway through the chest wall into the pleural space and the production of a sucking wound. Closed penetrations do not cause sufficient defect in the chest wall to produce sucking wounds but are frequently followed by pneumothorax and hemothorax, the blood most often coming from the chest wall and the air from a rupture of the lung.

Non-penetrating chest injuries vary in severity from superficial abrasions to massive crushing injuries causing instant death from rupture of the heart or great vessels. In many, although the skin has not been disrupted, sharp rib fragments have traversed the parietal pleura and lacerated the lung, and we have the same hazards of hemothorax and pneumothorax as beset closed penetrations. One great difference between penetrating and non-penetrating thoracic injuries is the hazard of bacterial contamination associated with the penetrating wounds. Modern antibiotics have significantly diminished this distinction, and empyema is no longer greatly feared in open thoracic wounds.

Many of the other formerly hazardous complications of thoracic injury have become easily managed problems with our better understanding of their physiological facets and the ease and safety of modern thoracotomy. Pneumothorax is quickly and easily handled by inserting a catheter through an interspace and sucking out the intrapleural air by motor suction of sufficient volume to stay ahead of the leak in the lung and thus re-establish negative intrapleural pressure. Re-expansion of the lung will bring the leaking visceral tear into contact with the parietal pleura and its adherence here promptly seals it off.

Hemothorax is best aspirated early and should be aspirated completely and as soon as possible before clotting can occur. The old fear of reactivation of bleeding by re-expansion of the lung is unfounded as a lacerated lung is seldom the cause of extensive hemothorax, and where it is, once the bleeding has stopped, it will remain so due to the low pulmonary blood pressure. Persistent bleeding is from torn systemic arteries, usually the intercostals, and may require thoracotomy and ligation. Clotted hemothoraces are easily evacuated by thoracotomy, and decortication of the lung allows its re-expansion.

Severe crushing injuries of the chest, however, present problems not so readily solved. The disruption of the structural stability of the thoracic cage by multiple rib fractures often makes adequate pulmonary ventilation impossible. Contusion of the lung adds further difficulties, and cardiac contusion may result in serious arrhythmias. An understanding of the nature of the physiological disturbances associated with crushing injuries points the way, however, to their successful management.

Acute pulmonary edema of some degree occurs in these injuries. Even though no ribs are fractured, as may occur in a young person with flexible ribs, severe contusion will produce almost immediate massive pulmonary edema. The exact mechanism of this phenomenon is unknown, but it is probably related to anoxia and the resultant pulmonary hypertension. Drinker has shown that the easiest and quickest way to produce pulmonary edema in dogs is by anoxia, and recently Cournand has demonstrated that anoxia results in significant increase in pulmonary blood pressure in normal adult males. Dr. Newell Wood, working at the Minneapolis Veterans Hospital, has demonstrated a marked reduction in oxygen absorption by the lung on the side of a single rib fracture even though its ventilation remains normal. Apparently as a result of even minor chest injury perfusion of the lung is reduced with concomitant diminished gaseous exchange; anoxia and hypercarbia follow with pulmonary hypertension and edema.

Read at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, May 26, 1952.

The treatment of traumatic wet lung is adequate oxygenation. If normal ventilation is possible, oxygen alone will suffice. If pain is immobilizing the chest, its relief by local procaine block may be required. Frequently the serous exudation into the lungs will be so great that tracheobronchial catheter aspiration will be necessary before adequate airway can be re-established, and coughing must be stimulated to continue the airway toilet.

Crushing injuries producing a flail chest wall present a more difficult problem. In addition to the wet lung, we now have a chest wall that sucks in on inspiration and bulges out on expiration and so is said to be moving paradoxically. The patient now sucks his chest wall in and out of the thoracic cage rather than air in and out of his lungs. Tidal air is sharply reduced and coughing is impossible. Traumatic wet lung is also present, and pleural complications of hemothorax or pneumothorax may be expected. If the pulmonary injury is severe, hemorrhage into the lung with loss of alveolar tissue to respiration and bronchial obstruction by clots further impedes ventilation. This patient may be salvaged by stabilization of the chest wall and the re-establishment of adequate ventilation. If the chest wall injury is not too extensive, is unilateral, and the contralateral lung is uninjured, firm circumferential strapping will stop the paradoxical motion, allow effective diaphragmatic ventilation, and permit good coughing. Pleural complications must be effectively handled and the compressed lung fully re-expanded. A clear airway must be promptly obtained either by effective coughing or catheter aspiration of the tracheobronchial tree and this maintained.

Extensive unilateral crushing injuries of the chest and bilateral injuries cannot be stabilized by strapping. We have tried lateral traction attached to multiple ribs and discarded it. Tracheotomy with oxygen delivered under slight positive pressure during all phases of respiration will stabilize these chests. This accomplishes two things. The tracheotomy reduces the dead air space of the nose, mouth, and pharynx and allows better alveolar ventilation. Positive pressure oxygen delivered through this tracheotomy tube during expiration washes out the alveolar air delivered into the airway above the tracheotomy tube and, thus, completely eliminates this as dead air space, and oxygen delivered through the tube at positive pressure during inspiration prevents the intrathoracic pressure from falling below atmospheric pressure during inspiration.

The lungs and thorax, having inherent elasticity, can be ventilated very well, just the same as a balloon, without the help of a single rib if the air need not be sucked in, or, in other words, if intrathoracic pressure need not fall below atmospheric pressure for air to enter the lungs.

The tracheotomy also provides an easily available port for aspiration of the tracheobronchial tree, and since it makes high intrapulmonary gas pressures impossible, as in straining or coughing, it hastens the closure of air leaks from tears in the lung. Because of this a tracheotomy will promptly control a spreading subcutaneous or mediastinal emphysema.

Occasionally, multiple anterior bilateral rib fractures or costochondral separations will leave the sternum floating. It then sucks in on inspiration and bulges forward on expiration. This is easily stabilized by traction. A Parham band may be placed beneath it and attached to pulley-weight overhead traction of about 4 pounds for an adult, or it may be grasped by tongs and traction applied. Towel clips inserted into the cartilages are painful.

The aim in every chest injury is the prompt re-establishment of adequate ventilation. Oxygen is essential to support life till this is accomplished, but a patient must also eliminate carbon dioxide, and if dyspneic or hyperpneic though pink, exchange is inadequate and respiratory acidosis is present. Quiet respiration on room air with good color and effective cough is the goal.

SUPPLEMENT TO MOTION PICTURE REVIEWS AVAILABLE

The Committee on Medical Motion Pictures of the AMA has completed the fourth supplement to the booklet entitled "Reviews of Medical Motion Pictures." It contains all the film reviews published in *The Journal* from January to December, 1952.

One copy has been mailed to the secretary of each state medical society. Copies are available to county medical societies on request from: Committee on Medical Motion Pictures, American Medical Association, 535 North Dearborn Street, Chicago 10.

CHRONIC PHARYNGEAL AND LARYNGEAL HISTOPLASMOSIS SUCCESSFULLY TREATED WITH ETHYL VANILLATE

A Case Report

HORACE H. ZINNEMAN, M.D., and WENDELL H. HALL, M.D.
Minneapolis, Minnesota

ONLY eighteen probable or proved cases of histoplasmosis, originating in Minnesota, have been reported to the Minnesota Department of Health since 1926. Six of these cases were reported in 1950 in MINNESOTA MEDICINE as an unusual type of pulmonary disease involving six members of a family at Detroit Lakes.[22] Subsequently, all of the six were found to have histoplasmin skin sensitivity as well as serum complement-fixing antibody. Moreover, *Histoplasma capsulatum* was cultured from the dust of the basement of their home.*

The present report deals with a case of histoplasmosis which appears notable because of its chronicity, the histologic proof of the diagnosis and the successful therapy with ethyl vanillate.

Case Report

A forty-two-year-old white machine operator noted the gradual onset of hoarseness in the spring of 1950. Local therapy with tincture of iodine was of no avail, and by September, 1950, he became increasingly short of breath. A choking spell necessitated an emergency tracheotomy. Following the operation, his voice began to improve and was almost normal by the spring of 1951. Very gradually he again became hoarse and by February, 1952, his voice had diminished to a whisper. He also noted intermittent episodes of fever. He lost 25 pounds of weight and encountered considerable difficulty in swallowing because of soreness of his throat. He had lived in or around Duluth, Minnesota, all his life except during World War II. From 1943 to 1944 he saw action as a soldier in North Africa and Italy. His past history was otherwise irrelevant.

The patient was afebrile, alert, but poorly nourished, weighing 128 pounds, and unable to speak above a whisper. Externally the head and neck showed nothing of note. There was generalized swelling and reddening of the mucosa of the hard palate, maxillary gingiva, tonsillar pillars, uvula and the posterior pharyngeal wall. The mucosa was granular in appearance and of spongy consistency. There was no ulceration. Similar lesions also were noted in the larynx; the vocal cords were greatly swollen, granular and covered with a dirty grey exudate. The heart and lungs were not remarkable; the blood pressure was 95/70 mm. Hg. The liver, spleen and kidneys could not be palpated. The rectal examination was negative. There were no skin lesions.

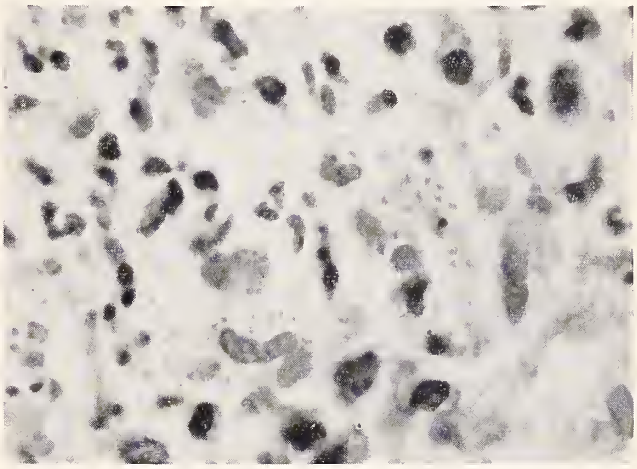

Fig. 1. Biopsy specimen from the hard palate stained with hematoxylin-eosin, showing submucous tissue filled with chronic inflammatory cells and including several macrophages with intracytoplasmatic yeast cells having a distinct clear capsule. Microphotograph, magnification ×396.5.

Laboratory Data.—The initial urine was not remarkable. The hemoglobin was 14.1 gm./100 cc., and the leukocyte count was 4000/c.mm. with 58 per cent neutrophils, 34 per cent lymphocytes, 3 per cent monocytes, 3 per cent eosinophils and 2 per cent basophils. The erythrocyte sedimentation rate was 38 mm./hr. The total proteins measured 8.1 gm./100 cc. with an albumin fraction of 3.1 gm. and globulin 5.0 gm. The globulin fraction was composed of alpha globulins 1.5 gm., beta globulins 1.4 gm. and gamma globulins 2.1 gm./100 cc. Liver and kidney function tests were normal. Sputum cultures were negative for acid-fast organisms and fungi. The spinal fluid was normal. A sternal bone marrow biopsy presented one isolated nonspecific granuloma. Two of four biopsies of the mucous membrane of the palate and pharynx revealed the characteristic histologic picture of histoplasmosis (Fig. 1). The lesions showed masses of chronic inflammatory cells with occasional giant cells of the Langhans type. A few foci of macrophages with many intracytoplasmatic capsulated yeast cells, presenting a double-contoured capsule, were seen immediately beneath the epithelium.** The

*Information obtained from Dr. C. B. Nelson, Minnesota Department of Health, Minneapolis.

**Histologic diagnosis and description by Drs. E. T. Bell and D. F. Gleason.

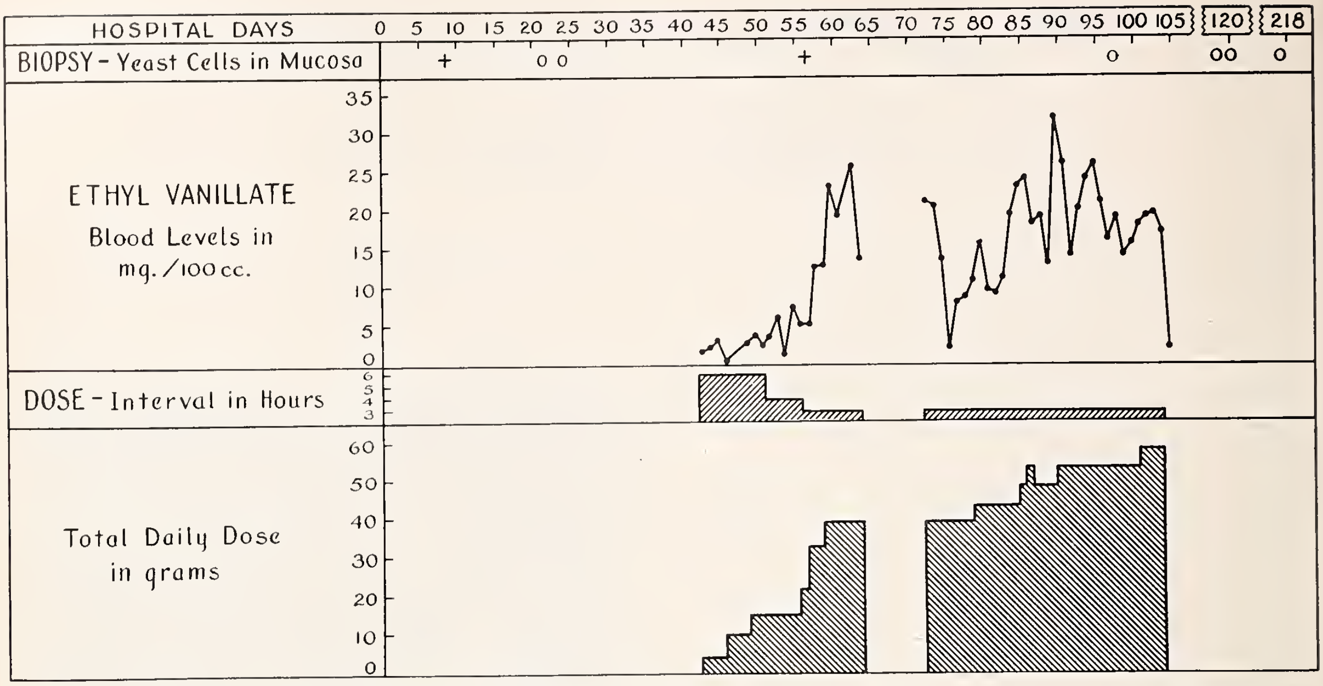

Fig. 2. Results of mucosal biopsies and treatment with ethyl vanillate in a patient with chronic pharyngeal and laryngeal histoplasmosis.

biopsy material was too limited to permit further staining procedures. Attempts to isolate the yeast from the biopsy material by culture and inoculation into mice and guinea pigs were unsuccessful. Radiologic examinations of the chest and the gastrointestinal tract were entirely normal. Proctoscopy was negative.

Hospital Course and Treatment.—Oral therapy with ethyl vanillate† was begun on April 16, 1952, using gelatin capsules containing 0.6 gm. of the drug. Satisfactory blood levels were obtained when the drug was administered every three hours. Adequate levels (20 to 30 mg./100 cc.) were obtained when the dose amounted to 4.8 to 6.6 gm. every 3 hours. It was not possible to maintain the blood concentration at a constant level (Fig. 2).

There were few side effects from the drug. Gastric and pharyngeal irritation was minimal in spite of the large dose. There was a temporary but mild reduction in the excretion of phenolsulfonphthalein. At therapeutic doses a copper-reducing substance appeared in the urine. The latter was not fermented by yeast and the blood sugar remained within normal limits. Of the liver function tests, only the thymol turbidity test became elevated (22 units) during therapy, and later it returned to normal.

The granulomatous papular lesions had almost disappeared by May 15. The mucous membranes of the hard palate remained somewhat spongy. The patient still spoke in a whisper, but was able to swallow normally and eat a general diet. Interruption of therapy from May 6 to May 15 was necessitated by temporary exhaustion of our supply of ethyl vanillate.

At the end of therapy the erythema and the granular lesions, as well as most of the gingival sponginess, had disappeared. Biopsies from the hard palate, the vocal cords and the pillars, taken on June 9, August 1 and November 6, 1952, contained chronic inflammatory granulomatous tissue without evidence of yeast cells and from which no yeast growth could be obtained by culture or mouse inoculations. The larynx was of normal dimensions and color; however, the vocal cords presented extensive scarring.

The patient was seen on follow-up examinations in August and November of 1952 and no further lesions were noted. He still had a hoarse voice. All laboratory tests were normal. The patient had been working, had gained six pounds in weight and had not experienced any febrile episodes..

Comment

The first two cases of histoplasmosis were described by Darling[6,7,8] in 1905 and 1906. Since it was believed to be a tropical disease, histoplasmosis escaped detection elsewhere until 1926, when Watson and Riley[24] described the disease in a fifty-two-year-old woman who had spent most of her life in Minnesota and never had been in tropical or subtropical regions. As with Darling's patients, she had an irregular fever, leukopenia, hepatomegaly and an unresolving bronchopneumonia ending fatally.

Watson's report transferred the interest in histoplasmosis from the tropics to the North American continent; in 1934 Dodd and Tompkins[11] reported the first case diagnosed *ante mortem.* The material from that case was studied culturally by deMonbreun,[9] who identified the causative agent, *H. capsulatum,* and demonstrated its life cycle as a yeast with mycelial stages. Darling had thought the organism to be protozoan.

---

†Generously supplied by Dr. Harvey Blank, E. R. Squibb & Sons, New York, New York.

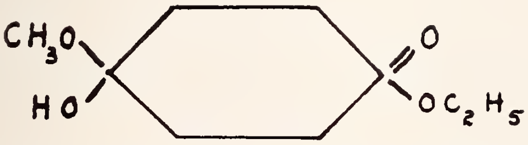

Fig. 3. Chemical structure of ethyl vanillate.

The natural reservoirs of *H. capsulatum* are the soil,[13,17] dogs,[10] wild rats, skunks, opossums and cats. In general, animals seem to recover from the infection. A systematic survey of dogs in Minnesota for histoplasmosis has not been undertaken. To our knowledge only one dog in Minneapolis is known to have died of the disease.

Among human beings in Minnesota the incidence is relatively low. Only 4.7 per cent of 971 student nurses in a Minneapolis survey were positive histoplasmin reactors, as compared to 13.8 per cent in Detroit, Michigan, 11.8 per cent in Philadelphia, Pennsylvania, 50.2 per cent in Kansas City, Kansas, and 61.5 per cent in Kansas City, Missouri.[20] Recent extensive studies have established the Mississippi valley and the western slopes of the Appalachians as the most important areas for human infection. There the majority of children (up to 83 per cent) were found to have pulmonary calcifications, previously thought to be tuberculous. Yet less than 50 per cent of these children had a positive tuberculin skin test. After the introduction of the histoplasmin skin test, they were found to be positive histoplasmin reactors.

Until recently human histoplasmosis was thought to be always a widely disseminated and fatal infection. Present evidence indicates that this is not true. Kunstadter,[19] Bunnell and Furcolow,[1] Stuart et al,[23] Curtis and Grekin,[5] Friedman et al,[14] Furcolow[15,16] and Christie[2] have characterized the disease as usually a benign, self-limited pulmonary infection, often ending in multiple, nodular calcifications in the lung. Christie[3] and others have also described intermediate, chronic infections which, like the present case, often are localized in the pharynx and larynx.

H. capsulatum may invade any tissue of the body. With disseminated infections the organs are involved in the following order of frequency: lymph nodes, lungs, adrenals, gastrointestinal tract, bone marrow, skin, mouth and larynx, pancreas and kidneys.[21] The frequency of adrenal involvement is noteworthy. At autopsy the greatly enlarged adrenal glands, which for the major part consist of necrotic tissue, frequently show no parasites. Destruction of the adrenal glands has been a frequent cause of death; indeed, any case of Addison's disease of unexplained etiology should be evaluated for histoplasmosis.

Histologically, the typical lesion consists of granulomatous tissue, containing numerous macrophages and giant cells. The intracellular parasite may be missed unless the histologic sections are studied under oil immersion. From one to thirty yeast cells may be seen in a single phagocyte. They measure 1 to 3 μ in diameter and characteristically have a double refractive capsule. Although the parasite can be seen in hematoxylin-eosin stains, it is better demonstrated with Giemsa or periodic acid stains.[2]

Infection with *H. capsulatum* may be acute or chronic and may be seen in any one of the following three forms: (1) Progressive, active histoplasmosis. (2) Asymptomatic benign infection, healing spontaneously. (3) Histoplasmin sensitivity of the skin, without demonstrable lesion.

Clinical signs and symptoms may present themselves in any combination of the following: irregular fever, anorexia, nausea, anemia, leukopenia (leukopenia with splenomegaly is typical and often simulates aleukemic leukemia); pulmonary infiltrates, occasionally with cavitation; hepatomegaly, splenomegaly, generalized lymphadenopathy; ulcerations of the skin or mucous membranes, particularly the oropharynx; chronic diarrhea, simulating ulcerative colitis; and Addison's disease.

Until recently all therapeutic efforts have been unsuccessful. Within the past two years, however, ethyl vanillate (Fig. 3) has been demonstrated to be an inhibitor of the yeast *in vitro* and *in vivo.*[4,18] The ethyl ester of vanillic acid, a by-product of the manufacture of sulfite pulp, is a colorless crystalline solid with a melting point of 43 degrees C., of cinnamon-like taste, insoluble in water, but soluble in alcohol and propylene glycol, and readily miscible in oils. *In vitro* the yeast form of *H. capsulatum* is inhibited by ethyl vanillate in concentrations of 20 mg./100 cc.

The drug is a local irritant to mucous membranes; toxic doses result in liver and kidney damage. The margin of safety is narrow. Toxic reactions make their abrupt appearance in the human being when blood levels exceed 50 mg./100 cc., and levels between 20 and 30 mg./100 cc. are desirable for successful therapy.[4] The substance is rapidly excreted in the urine and feces. In the present case blood levels varied considerably even when ethyl vanillate was given at three-hour intervals. After one single dose the blood level reached its peak in three hours, then gradually dropped off and became negligible after seven hours. Initial doses should be small and increased gradually until satisfactory blood levels are attained. Therapeutic levels will be reached in adults with a daily dose of about 0.8 gm./kg. Children require almost twice that amount.

Christie and his group[4] stated that after one week's treatment at adequate blood levels the yeast disappears from the tissues, but that longer periods of treatment may be necessary for cure of the disease. Five out of twelve severe cases of the disseminated type of histoplasmosis in their series recovered with ethyl vanillate therapy.

Local therapy of the pharyngeal lesions of histoplasmosis with propamidine has been successful in one case reported by Ellis and his associates.[12] Propamidine is a p.p′-trimethylenedioxy-dibenzamidine, a substance related to stilbamidine, and may prove to be a valuable addition to the therapeutic armamentarium against histoplasmosis. Ellis used 0.1 per cent propamidine in normal saline solution as a local spray and combined it with local applications of 100,000 U. of streptokinase and 25,000 U. of streptodornase in 10 cc. of normal saline.

Summary and Conclusions

A patient with chronic pharyngeal and laryngeal histoplasmosis, apparently originating in northern Minnesota, was treated successfully with ethyl vanillate. A brief review of the general nature of histoplasmosis and its current treatment has been given.

PREMATURE SURVIVAL

With Emphasis on the Role of the Public Health Nurse

S. S. SCHERLING, M.D.
Minneapolis, Minnesota

ALTHOUGH there has been a continuing decrease in infant mortality during the past quarter of a century, the death of newborns and of infants under one year of age is still considerable. This paper is presented in the belief that a large number of these deaths might be prevented through a well-planned program, combining the skills of the physician, nurses specially trained in care of prematures, and public health nurses.

In the state of Minnesota, with an enviable infant mortality rate of twenty-five per 1,000 live births for the year 1950, there were 1,874 deaths under one year of age. For the same year, over 110,000 infants one year or under died in the United States. Further statistical analysis reveals that from 35 per cent to 50 per cent of infant deaths are due to prematurity and in 1948 over 39,000 deaths were caused by prematurity.

Prematurity ranks first as the cause of death in the first year of life and eighth among the leading causes of death in Minnesota. There are as many deaths in the first year of life as the total for the next thirty-nine years. It is apparent that if infant mortality is to be reduced further, more intensive studies and research on the problems of prematurity will have to be undertaken.

The approach to this serious problem may be taken along two lines: first, preventing premature births; second, providing better medical and nursing care for the premature infant.

Prevention properly belongs in the hands of the obstetrician and the general practitioner. Providing better care is the concern of the physicians and nurses caring for newborns at the hospital, as well as of the public health nurse. It has been said that over two-thirds of the prematures who die could be saved with improved medical and nursing care and proper follow-up.

But first we must dispose of the question repeatedly asked, "Are prematures worth saving?"

If we were to look for the answer in the older literature, the outlook would indeed be gloomy and disheartening. Capper's stated views, based on statistics from Pirquet's Vienna clinic, are even more pessimistic than those of Ylpöe and of Brander, whose work he reviewed. Capper states in an article published in the *American Journal of Diseases of Children* in 1928: "Even more impressive (than the fact that these children have not caught up to full-term children in weight and height by puberty) are the deviations from normal in their physical and mental progress. In brief, the immature infant will become the backward school child, is the potential future psychopathic or neuropathic patient and even the potential inmate of the home for imbeciles and idiots." It is surprising that these authors would reach such conclusions in face of the known fact that such great men as Isaac Newton, Darwin, Napoleon, Voltaire, and Victor Hugo were small prematures.

Findings of recent studies are more encouraging. Moehr and Bartelme, in a well-controlled study with children from Dr. Hess's group, clearly showed that by four to five years of age no differences could be detected. The gratifying results of an analysis of 317 surviving infants ranging in weight from 605 to 1,280 grams, and in age from one to twenty-six years, was presented by Dr. Julius Hess at the meeting of the American Academy of Pediatrics in Chicago in 1950. Of 313 children whose birth weights were under 1,200 grams, the physical development of 258 was rated as "slight deviation based on expectation for age, as normal, or superior." An estimate of mental development showed 274 as normal and some superior. Only eight were subnormal and seven rated bad. Physically, four were rated as markedly subnormal and twenty-one bad. The actual number of subnormal and bad ratings was not as numerous as it appears, since those with low mental development are also included in the subnormal physical development group.

A similar study to determine what happens to the premature was undertaken by Koenig and associates at the New York Hospital, Cornell

---

Presented at Refresher Course for hospital and public health nurses at Center for Continuation Study, University of Minnesota, November 18, 1952, under auspices of Minnesota Department of Health.

Medical Center. These children were studied at frequent intervals over a period of two to ten years. Not only physical growth, but also speech development, locomotion, self-care, toilet training, school attainment, and social adaptation were measured. It was noted that even in the smallest weight group, average growth was attained, although it was at a later age. Most of the children were not adversely affected by prematurity.

Weighing all the evidence, the logical conclusion is that the small premature is worth saving, and that all measures taken to effect its survival are not only justifiable but mandatory.

However, all articles and surveys on the premature program agree that there is a notable lack of proper instruction given to parents of premature babies. As a result, too often the careful, meticulous, time-consuming effort expended in nursing a premature through the perilous early days in the hospital is nullified when he is discharged at 2,500 grams to an unsuitable home environment, and to parents unable and unprepared to care for so small a baby.

Many fears, misconceptions and undue anxiety of the parents can be dispelled by repeated, detailed instructions, frequent home visits, and conscientious medical supervision. The busy practitioner is too involved and has too little leisure to devote the time needed for such instruction. However, if he desires, he has within easy reach the public health nurse, who is not only able but anxious to perform these much-needed services.

While the baby is still in the hospital, the nurse makes her first visit to the home. At this visit she can instruct the parents in detail and answer many of the questions that trouble them. She surveys the household and if possible arranges for a separate room for the infant. If the house does not lend itself to such an arrangement, she manages to screen off the least used corner of the most suitable room for the baby. She can explain the need to avoid infections by eliminating visitors, frequent washing of the hands, and avoiding unnecessary or too frequent handling of the baby. The nurse advises as to procedure for airing and ventilation of the room while taking measures to protect the infant. Finally, at this visit, she inspects the siblings for evidence of infection. To be effective, this examination must be repeated just before the baby is to be released from the hospital.

Soon thereafter the nurse again makes a home visit. She reassures the family, counsels the parents regarding room temperature and clothing of the infant, and explains the danger of soft bedding. By actual demonstration she points out bathing and feeding techniques and the fundamental details of nipple care, sterilizing bottles, formula preparation, bubbling the baby, and a host of simple techniques with which the average parent is not acquainted. Finally, the trained nurse alerts the parents to observe changes that may be significant and may demand medical attention. She stresses the importance of continued, regular medical examinations, and if necessary arranges for them.

By her sympathetic approach, her sincerity, and her obvious desire to be of help, the nurse gains the confidence of the parents and becomes aware of any nettlesome family problems. With this information, and with the family consent, she is in a position to call upon existing social agencies to help the family solve their difficulties.

But in order to carry out such a program, the doctor as well as the nurse must have training in premature care and an understanding of the handicaps of the premature infant. To meet this obvious need a number of states have established special centers for prematures, under the direction of the health department. In New York City a joint training program for pediatricians and nurses was arranged through the co-operation of the State Department of Health, the U. S. Children's Bureau, and the City Department of Health. Teams of doctors and nurses were trained together, then returned to their respective hospitals to institute a well-planned, properly supervised program for premature babies. Other states have done the same through their state boards of health.

Such a training program established in this state would enhance the survival rate of premature infants. For the present, co-operation between the physician, the health department, and the public health nurse would solve many difficult family problems that parents of premature infants may encounter. Such difficulties as poor housing, tensions, and neglect of other children could be easily solved through team work and co-operative effort of the physician, the public health nurse, and established social agencies.

The Minnesota Society of Clinical Pathologists

CLINICAL DETERMINATION OF HEMOGLOBIN

FRANK D. MANN, M.D.
Section of Clinical Pathology, Mayo Clinic
Rochester, Minnesota

THE DETERMINATION of hemoglobin is one of the procedures most frequently requested of the clinical laboratory and it is also one whose results are questioned more frequently than almost any other. It would appear appropriate to inquire whether or not the procedures available for the determination of hemoglobin in the clinical laboratory are basically sound.

Virtually all clinical determinations of hemoglobin are performed by some colorimetric method. Most of these techniques involve three basic steps: (1) measurement and dilution of blood; (2) conversion of hemoglobin into some pigment suitable for optical determination and (3) determination of this pigment of hemoglobin. These steps form convenient headings under which the subject may be considered.

The principal source of error in the measurement of blood, aside from faulty performance of the mechanics of pipetting, is inaccuracy of the micropipettes that are used ordinarily. Reports have appeared which indicate that the calibrations of some such pipettes on the market were in error by as much as 30 per cent.[1] These were mainly pipettes manufactured near the end of World War II; pipettes currently available from recognized manufacturers appear to be accurate. The possibility that such inaccuracies might appear again must be borne in mind and guarded against by spot checking of calibrations.

Several different pigments of hemoglobin have been used in clinical determinations. Probably those most commonly employed have been acid hematin and oxyhemoglobin. The wide acceptance that has been accorded methods using acid hematin is difficult to understand, because it has been known since the work of Wu,[5] in 1922, that this substance is greatly affected by plasma. Hence all methods that use acid hematin are subject to large uncontrollable errors except those relatively laborious procedures based on use of washed erythrocytes. Oxyhemoglobin is highly unstable in the dilutions required for hemoglobinometry. The alterations that it undergoes do not result in changes in determined values until one half to one hour after dilution; after this, variations of the order of magnitude of 5 to 10 per cent are common.

Cyanmethemoglobin, on the other hand, is a pigment that remains entirely unchanged in spectral-absorption characteristics for twenty-four hours or more at room temperature. As shown by Sunderman, this pigment can be prepared as readily as acid hematin or oxyhemoglobin simply by dilution of blood with a solution containing 100 mg. of sodium cyanide and 300 mg. of potassium ferricyanide per liter. Because of the dread associated with anything containing cyanide, this solution has been criticized as dangerous. Actually this highly dilute solution of cyanide is less toxic than the Hayem's solution routinely employed as a diluting fluid for erythrocytes; it is just as unlikely to be inadvertently ingested in appreciable quantity. Evaluation of the extensive spectrophotometric measurements of Drabkin, together with the work of Sunderman and of Turner,[4] indicates that cyanmethemoglobin is the pigment of choice for the determination of hemoglobin; the writer has confirmed this in six years of clinical use, involving more than 750,000 determinations.

For the actual optical determination of hemoglobin, photoelectric instruments are widely used, just as they are in the majority of determinations in clinical chemistry. It may be generalized that virtually all commercially available photoelectric filter photometers and spectrophotometers are capable of yielding accurate results when they are properly used. Because the optical systems of most of these instruments permit a considerable amount of stray light, empiric calibration is required with blood that contains known amounts of hemoglobin as determined by an independent method. Three such methods are available: (1) oxygen capacity (Van Slyke); (2) determination of iron and (3) direct spectrophotometric determination.

The third of these methods is probably the most convenient, but it requires a spectrophotometer of sufficient resolving power so that stray light is negligible. I use both the first and third methods in order to have the added security of two independent techniques. Photoelectric colorimeters and spectrophotometers often are purchased with calibrations supplied by the manufacturer. While the use of such calibrations does not necessarily lead to error, it does encourage a false sense of security on the part of any technician who may be inadequately informed about the principles of the method. Anyone competent to use these instruments should be competent to calibrate them and should do so. For anyone concerned with photoelectric photometers, the work of States[3] on the subject of stray light may be highly recommended.

In the routine operation of single-photocell colorimeters and spectrophotometers, the most common difficulty that is not covered by instructions from the manufacturer is excessive fluctuation in voltage and frequency of the alternating current used. The plain fact is that many of those instruments as supplied will not operate at all satisfactorily on the electric power available in many localities. Unless a source of highly constant current is available, either electronic voltage regulators or storage batteries are absolutely required. The latter are inconvenient and the former expensive, which may possibly explain why manufacturers of photoelectric instruments have not informed their customers that they are often required. This difficulty cannot of course be charged to the method employed in the determination of hemoglobin.

When the individual steps in the clinical determination of hemoglobin are examined, as just outlined, no basic fallacy in the method can be detected. All manipulations are simple and based on proved principles. However, it follows from the laws of biometry that any procedure, however simple, occasionally will give rise to errors far larger than the average error; these instances occupy the extremes of the statistical distribution curve. The number of determinations of hemoglobin performed in a busy clinical laboratory is so large that the laboratory will surely be damned by at least occasional errors of apparently inexcusable magnitude. Deficiencies encountered in simple articles of commercial manufacture, the products of highly refined, automatic, machine processes, provide everyday examples of the inevitability of a certain incidence of error. It is much harder adequately to control the product of the clinical laboratory, which ends up as only a number on a piece of paper, than a manufactured article. The studies of Magath, Berkson and Hurn[2] on determination of erythrocytes have illustrated methods of attack on such problems that no doubt will be applied eventually to all frequently performed procedures in the clinical laboratory. The main problem in the determination of hemoglobin is thus merged into a general one, which dominates all work in clinical laboratories and in other fields that involve large numbers of routine individual operations.

This is the third in a series of editorial reports sponsored by the Minnesota Society of Clinical Pathologists and designed to emphasize ways in which laboratory methods may aid in the practice of medicine. Determinations of hemoglobin are performed frequently as office procedures; many different techniques are utilized and it is taken for granted that the results, which often sway important decisions in therapy, are accurate. Yet it is an easily forgotten fact that, even under the best of conditions, results of determinations of hemoglobin may vary tremendously. Therefore, the committee welcomes this report by Dr. Mann, who has had an extensive personal experience in hemoglobinometry.

As emphasized in the two preceding contributions of this series, the physician who specializes in pathology holds himself available at all times for consultation; he hopes that other physicians will feel free to seek him out for any aid he may be able to render in the advancement of medical practice. The editorial committee, consisting of Dr. Arthur H. Wells of Duluth and Drs. Arthur H. Sanford and George G. Stilwell of Rochester, solicits suggestions and comments concerning these reports. In most instances, reprints will be available and may be obtained from either the individual author or the chairman of the committee.

President's Letter

VIEWING FOR HEALTH

Remembering the tremendous following developed by Dr. William A. O'Brien in his many years of radio broadcasting on health matters, it is gratifying, but not surprising that the University of Minnesota became interested in developing a series of television programs along educational lines.

And, as in the case of Dr. O'Brien's broadcasts, the Minnesota State Medical Association was consulted, asked for advice and support.

The Council, in discussing the request, expressed the view that health talks can do great good for people anxious for knowledge about their own and their community's health. With this in mind, the Council assured the University of its co-operation in the initiation of health telecasts.

As a public service, WCCO-TV offered a weekly half hour on Monday mornings from 10:00 to 10:30 for a period of thirteen weeks, which began February 9. Because of this, it was possible to sponsor such a series for the entire thirteen weeks, which would have carried prohibitive costs if contemplated on a commercial basis.

It should be noted that all programs are being supervised for scientific accuracy prior to their televising. Doctors in each field of discussion were called in to aid the producers with subject matter and its treatment. The entire series is also being supervised by the Association's Committee on Public Health Education, through its radio and television committee.

The subject material is largely of a general health nature, stressing problems commonly occurring in everyday life in the home. Personnel on the program are not doctors engaged in the private practice of medicine, and supporting personnel are being drawn from the University's school of dramatics. The staff of the University's radio station, KUOM, with the use of the time and facilities of WCCO-TV, is developing the series.

We feel that Minnesota is one of the leaders in initiating this new project. Telecasts on health matters are a relatively new departure for organized medicine. There are a few similar shows currently running in other areas of the nation, and the American Medical Association has telecasts on health subjects done by professional television writers and producers.

The series is part of the continuing program of the Committee on Public Health Education to reach the public with information on important matters of health.

With the success of this Minnesota series, it is seen that television can be a very valuable media by which medicine can further the development of a positive approach to health and medical matters.

THE STATE ASSOCIATION CENTENNIAL

ONE HUNDRED years ago on July 23, 1853, the Minnesota State Medical Association was founded. This we know, not from our own records, but from reports which appeared in newspapers of that year. *The Minnesotan* of Saint Paul in its July 16, 1853, issue states that the medical profession of the Minnesota territory would hold a convention in Saint Paul on July 23. The July 30, 1853, issue of the *St. Anthony Express* contains an account of the meeting in the Court House of St. Paul of nine physicians of the St. Paul-St. Anthony area (two others being present by request) and the formation of the Minnesota Medical Society. A constitution was adopted and officers elected.

Meetings were held until 1857, how many and how frequently is not definitely known. It is quite certain that none was held in the period from 1857 to 1869 when on February 1 the society was revived at a meeting held in the International Hotel in St. Paul.

When the Minnesota Medical Society was launched by the handful of physicians in the St. Paul-St. Anthony area, Minnesota was still a territory. The bill organizing the Territory of Minnesota was passed by Congress on March 3, 1849. St. Paul was to be the capital and had a population of 250 to 300 persons at that time. On April 28, 1849, the first issue of the first newspaper, *The Pioneer,* made its appearance. Governor Alexander Ramsey arrived by steamboat on May 27 and, because hotel accommodations were inadequate, he and Mrs. Ramsey became the house guests of the Hon. H. H. Sibley at Mendota. It was not until 1858, when on May 11 the President approved an act of Congress, that Minnesota became a state and H. H. Sibley was declared its first governor. He had been duly elected the preceding October in anticipation of statehood. In the fall of 1859, however, Alexander Ramsey was elected governor and took office in 1860.

It seems highly desirable that the centenary of our State Association should receive appropriate recognition. Although, strictly speaking, the meeting to be held in St. Paul, May 18-20, is not the 100th annual meeting, we are, as an association 100 years old.

The centenary will be the theme of the meeting. More than the usual number of out-of-state visitors will take part in the scientific program. Sir Alexander Fleming, of penicillin fame, will speak on "Antibiotics in Heart Disease," and Dr. Richard R. Trail will speak on "X-Ray of Chest Cancer." Both are from London and will also take part in the centenary celebration of St. Joseph's Hospital on May 16.

MINNESOTA MEDICINE plans to devote its April issue to a celebration of the Association's Centenary. A number of members have consented to write on the general theme of what a century has meant in their particular spheres of medical interest. The development of medical science the past 100 years, and more especially the past fifty years has been phenomenal. The art of the practice of medicine, on the other hand, has lagged. It should be most interesting to pause for a review of this progress on the occasion of our Centenary.

ST. JOSEPH'S HOSPITAL CENTENNIAL

THIS seems to be centennial year in Minnesota; a well-known insurance company, a bank, the Minnesota State Medical Association and St. Joseph's Hospital, all in St. Paul, will be one hundred years old this year.

It was in 1853 that the cornerstone to St. Joseph's Hospital in St. Paul was laid. In commemoration of the event, a one-day scientific session is planned for May 16, 1953, in the ballroom of the Hotel Lowry, St. Paul, Minnesota, at which time Sir Alexander Fleming, of penicillin fame, will be one of the speakers. Also, because the first successful cholecystectomy in America was done at St. Joseph's Hospital on September 24, 1886, by the late Dr. Justus Ohage, Sr., a symposium on diseases of the gall bladder will be held during the morning sessions. All doctors are cordially invited to attend these meetings. In the evening, a banquet will be held in the Hotel St. Paul, at which time Dr. Harold Foss, President of the American College of Surgeons, and Dr. Louis H. Bauer, President of the American Medical Association, will speak. This dinner meeting will be open to the public. The full program will appear in later issues of this journal.

Our congratulations to St. Joseph's Hospital, not only for being the oldest hospital in the State, but also, for the important part it has played in the care of the sick in St. Paul. The doctors and patients owe a debt of gratitude to the Sisters of St. Joseph's, who, by their courage, charity and spirit of self-sacrifice, have so faithfully run the hospital all these years.

The people of Minnesota salute you, St. Joseph's Hospital, and extend their best wishes to you for the next one hundred years.

PRESIDENT'S COMMISSION ON HEALTH NEEDS OF THE NATION

THE FIRST REPORT of the President's Commission appeared December 18, 1952. More volumes are to follow. The Commission was given a large order restricted to a limited period of a year, and has now announced its intention to continue in order to further clarify the results of its investigation. A mass of factual data was collected at the thirty all-day sessions in Washington and eight hearings outside of the capitol, on various phases of medical care.

Although the head of the Commission, Dr. Paul Magnuson, is a surgeon of ability and has had widespread administrative experience, numerous members of the Commission were known in advance to be socialist minded and the profession was skeptical from the start as to the conclusions which would be reached.

While the objective of the Commission, the betterment of the health of the American people, is the same as that of the medical profession, we cannot agree that the answer is for Uncle Sam to put his hands in his pockets and hand out more millions. After all, there is a limit to federal spending.

The Commission makes thirty-three recommendations for federal appropriations to be matched by equal amounts of the taxpayers' money to be supplied by the states. The program will require at least a billion of additional federal funds and another billion of state funds ($2,000,000,000 at least). Assuming this expenditure is desirable, can the national economy stand an additional 2 billions of taxation and governmental spending? This would mean further inflation and increases in cost of present medical care.

One of the Commission's proposals, that the 4.5 million beneficiaries of Social Security be provided with medical care through increase in taxes, means compulsory health insurance for this segment of the population, a policy contrary to the opinion of the Nation as expressed by thousands of organizations in the country and at the polls.

The federal government is at present spending millions of dollars in subsidizing hospital construction through the Hill-Burton Act and is showing little co-ordination by its construction of additional facilities for the Veterans Administration to care for non-service-connected cases which should be cared for in civilian hospitals. It thus furthers competition for already scarce hospital personnel between Veterans hospitals themselves and between Veterans and civilian hospitals.

The Commission further recommends the appropriation of federal funds not only for the construction and rehabilitation of medical school buildings but for the maintenance of the schools. The AMA has gone on record that acceptances of federal subsidy by medical schools, except in the form of one-time grants for construction purposes, endangers the future independence of medical training.

If the election last November meant anything, it meant a retrenchment in federal spending. We live in a critical age when our production and economy in general are being taxed to the utmost to defend our country from foreign aggression. It is no time to extend our socialistic trends. Once adopted, socialism is almost impossible to abandon.

Minnesota State Medical Association
George Earl, M.D., Chairman

AMA CRITICIZES COMMISSION REPORT

The official reaction of the Americal Medical Association toward the report of the President's Commission on the Health Needs of the Nation is seen in the January 24 issue of *The Journal of the American Medical Association.* The Board of Trustees issued a statement which summarizes its feeling about the Commission's accomplishments: "The Commission has little to offer that is new."

While the Board criticized the report, it did recognize certain difficulties under which the Commission had to work. The statement was issued with this qualification: "Comments on this report are made with the full understanding of the very wide scope of the assignment and the very limited time the Commission had to attempt to accomplish its task."

Solution: Federal Funds?

Nevertheless, the Board of Trustees did not limit its criticism on this account. It explained:

> "The Commission, by executive order, was required to submit its final report in one year. It has labored arduously and any cricitism of its final report must be made in the light of the tremendous scope of its assignment and the time limit on its activities. The Board, however, is not justified in withholding criticism on this account, since the impact of such a report, unless subjected to careful analysis, may carry undue weight in future discussions of the many important problems affecting the health of the American people."

The Board then stated its major objection to the Commission's recommendations: that the answer proposed for the solution to almost every problem is additional federal funds. And, the Board continues, "aside from the question of how these funds are to be raised, in the background of all of these endeavors lurks the shadow of federal control." Reiterating the danger of federal control further, the Board stated:

> "This control may come directly or by established standards to which all states must conform. These standards will not be written into the law but will be established by administrative regulations. If the pattern laid down in former bills is followed, the administrative agency will be authorized to set up a plan of its own, in any state that does not conform to federal standards."

Would Spiral Inflation

The fact that federal funds are recommended would only tend to spiral inflation, according to the Board of Trustees. It feels that because people are interested in higher quality medical care, and because millions are already covered by voluntary health plans, "an increase in federal expenditures leading to further taxation will give one more twist to the spiral of inflation and force a higher premium rate on those already protected." The Board comments further:

> "The philosophy behind this report is barren. While it gives lip service to the responsibility of the individual for his own health, it destroys this sense of responsibility by insistence on federal aid from every angle. While it stresses the importance of a personal physician, it demeans his standing by unfavorable and false comparisons of his ability to render good medical care as contrasted to the much vaunted groups of highly trained specialists."

Hits "All-Wise Government"

Noting that the report when first released, was devoid of factual supporting material, the Board says that the underlying philosophy is quite evident: "The argument is that health is conditioned by food, housing and education so that control of all of these factors, as well as health measures *per se,* should come under the direction of an all-wise federal government. Without naming it, the Commission has described the welfare state. It may be just as well to call it by its true name, the socialist state."

Federal Health Services Ignored

The Board pointed out that one of the commission's duties under the president's directive was to investigate the extent of federal, state and local government services in the health field and the desirable level of these expenditures considering private resources and other financial demands on government. However, there is little evidence in Volume I—the findings and recommendations—that the Commission has seriously considered this part of the directive under which it operated, according to the Trustees.

Reverse Order Criticized

At the time of the appraisal of the Commission's report, only Volume I was available, and Volume I was the Commission's final conclusions and recommendations. It is interesting to note this apparent reversal of order of issuing reports of investigating groups. "The scientific and logical approach would be the presentation of factual material, analysis of the data presented, comparison of this data with other material of like nature, presentation of conclusions on the basis of facts, and finally, recommendations as to action," the Board concluded.

The Board also noted certain inconsistencies and obvious ignoring or skimming of certain facts about the nation's health. In conclusion it stated:

> "The Board is fully aware that it is not in possession of all of the material that came before the Commission, and it awaits the publication of these facts, in the full report, before reaching final conclusions.
>
> "In Volume I, brief references are noted to the tremendous advances made by American medicine, in the last half century, without benefit of any large contribution from the federal government and without federal standardization.
>
> "The Board is therefore somewhat confused by the Commission's strong and repeated urging that the health of the American people can only be secured by widespread invasion by the federal government into almost every phase of medical activity."

EWING TRIP CALLED OSCAR'S "DEEP BOW"

"Oscar Awards Himself an Oscar" is the interesting title of a recent editorial from the *Chicago Tribune*. The article takes a swing at Oscar Ewing's recent pre-retirement swing to far parts of the world—a trip which Ewing justified as "a personal counter-offensive against communism."

The editorial describes the trip thusly: "The departing federal security administrator commanded himself to take a deep bow over his intrepidity, unselfishness and service to the nation in making a two-month trip abroad at the expense of the taxpayers."

The *Chicago Tribune* is not the only one concerned about the value of the journey. Some members of Congress, especially Rep. Gross of Iowa, were quite skeptical about the jaunt's benefits to the nation. Rep. Gross called it "a joy ride and last fling."

Ewing Rationalizes

According to the *Tribune* article, Mr. Ewing justified his trip as his personal counter-offensive against communism, and he said that Communists had been jeering that the United States had no social welfare programs for its citizens, and that by his personal appearances here, there, and everywhere, he was able to offset this foul libel. Comments the *Tribune,* "We are supposed to be thankful," and goes on to say, "It is a matter of staggering indifference to most Americans what the Communists say, and, in this particular matter many Americans would be just as content if the Communists were, indeed, correct in their statement that the United States has no social welfare programs."

> "Mr. Ewing is as one with the Communists in thinking that there is great virtue in handouts of every sort distributed by the state. That is the New Deal outlook, which is not essentially different from the communist outlook. Both philosofies seek all power for the state and endeavor to vest the state with benevolence by operating on the theory that if everybody is taxed into poverty the state will have the necessary revenues to dole out burocratic happiness to the greatest number."

In conclusion, the paper says, "The Eisenhower administration is said to be concerned with economy and reduced taxes. A good place to start the saving would be by requiring Mr. Ewing to pay his own frate, which will run into the thousands."

'54 HEALTH-WELFARE BUDGET ISSUED

The federal health and welfare budget proposals for fiscal 1954 have been issued recently, and they show some increases over the current fiscal spending, which ends on June 30. It should be noted, however, that these proposed figures represent the Truman administration's estimates, and they can be altered by the Eisenhower administration as seen fit.

Expenditures for the Veterans' Administration allow for 1954, a total of $774,000,000 ($691,000,000 for medical care, $83,000,000 for hospital construction), compared to a total of $763,000,000 for 1953 ($660,000,000 for medical care and $103,000,000 for hospital construction). It is noted that hospital construction is slightly less for 1954 while medical care costs are expected to rise. The hospital construction program costs are exclusive of Hill-Burton program funds, which come under the Federal Security Agency, Public Health Service.

Total expenditures for the Federal Security Agency for fiscal 1953, ending June 30, will be $1,545,974,000. Estimates for 1953 are $1,870,785,000. These figures are divided among: public assistance, Public Health Service, the Children's Bureau, Vocational Rehabilitation and Food and Drug Administration. Under the Public Health Service is control of venereal disease, control of tuberculosis, control of communicable disease, Hill-Burton hospital program, Cancer Institute, Heart Institute, Mental Health Institute, Arthritis and Metabolic Institute, Neurology and Blindness Institute, Microbiology Institute.

Civil Defense Administration budget figures have been increased more than double to include certain funds for federal stockpiling of civil defense materials. The Atomic Energy Commission funds are increased a little over $1 million. Funds for the Bureau of Indian Affairs have been increased about $6 million, while those for the National Science Foundation remain the same.

Total increase in expenditure estimates for health and welfare matters amount to approximately $400,000,000. The total figures for health and welfare in 1953 and 1954, respectively, are: $2,279,394,000 and $2,654,855,000.

FEWER APPLICANTS FOR MEDICAL SCHOOLS

Continuing a three-year trend, the number of students applying for admission to the nation's medical schools declined again this year, according to the official study of 1952-53 applicants by John M. Stalnaker, director of studies for the Association of American Medical Colleges.

Results of the study, reported in the February issue of *The Journal of Medical Education*, show that some 3,150 fewer persons applied this year than in 1951-52 and some 7,600 less than three years ago.

This means that competition among the medical schools for high-ranking student applicants is increasing. Of 16,763 persons who made application last fall, 7,778 were accepted.

The survey shows that the average pre-medical student applies to three or four medical schools, so that no school can expect to have every student they select. One cautious student this year applied to forty-five medical schools and was accepted by one.

Use of Alidase® Permits Subcutaneous Administration of Fluids at Usual Intravenous Rates

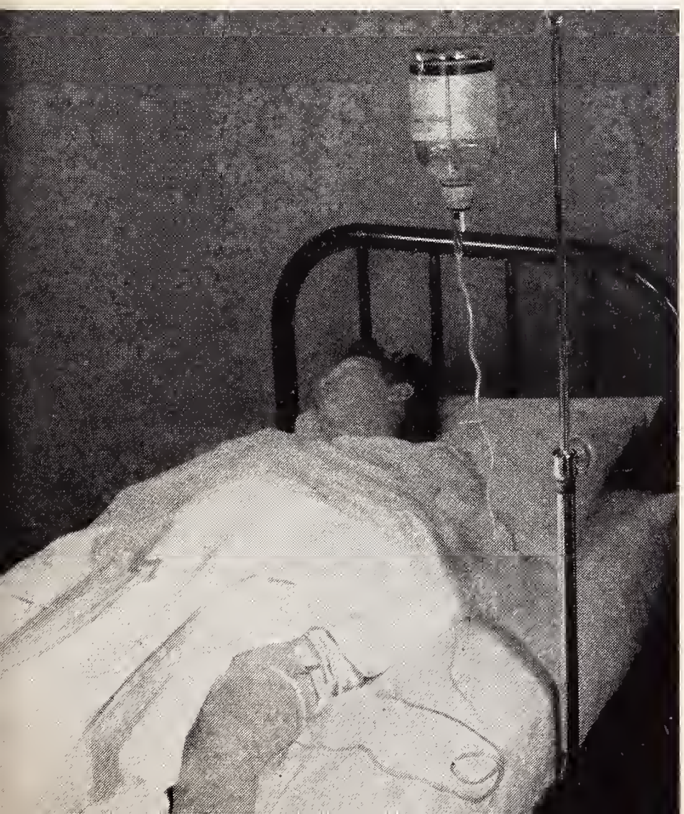
Addition of Alidase to the first few cubic centimeters of fluid during hypodermoclysis speeds absorption to a degree approximating that of the intravenous route. Use of highly purified hyaluronidase in this manner avoids the well-known difficulties encountered with venoclysis, saves valuable nursing time and is more comfortable to the patient.

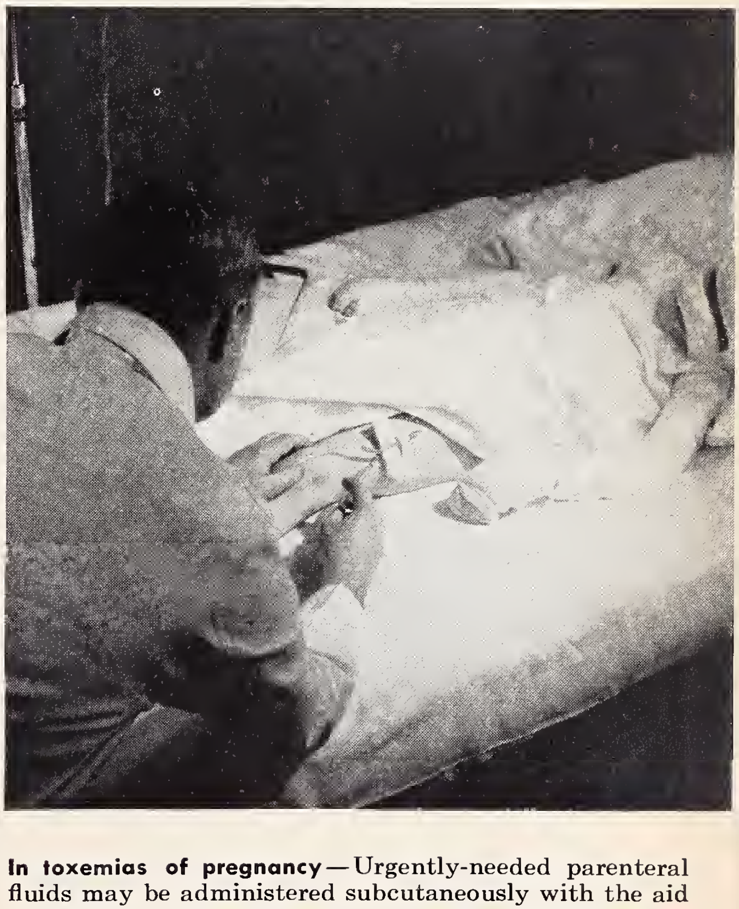
Hechter, Dopkeen and Yudell[1] have found that the use of hyaluronidase has "markedly increased the rates of absorption and administration of hypodermoclysis with no untoward reactions." They also found that extremely small amounts of this enzyme facilitated the absorption of fluids in that greater amounts of fluids were absorbed by the patient in a given period of time and that the localized swelling following hypodermoclysis disappeared more promptly.

Similar results with Alidase were recounted by Schwartzman, Henderson and King.[2] They observed "that absorption of various types of solutions, such as saline, glucose in saline, Hartmann's solution, Ringer's solution, penicillin, streptomycin, Adrenalin, and procaine was facilitated in every case."

In operative states—Alidase circumvents the complicating factors of venous thrombosis and "wornout" veins which frequently make fluid administration by vein difficult and dangerous. Simplicity and safety of Alidase make hypodermoclysis a method of choice for preoperative preparation and postoperative maintenance.

In burns—Plasma and electrolyte solutions can be given subcutaneously at effective rates when Alidase is employed; collapsed veins or risks of thrombosis are not a problem with this method.





In toxemias of pregnancy—Urgently-needed parenteral fluids may be administered subcutaneously with the aid of Alidase, eliminating risk of thrombosis attending repeated intravenous administration of electrolyte solutions. Alidase is the highly purified Searle brand of hyaluronidase and is accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

✦ Reports and Announcements ✦

CIVIL SERVICE POSITIONS AVAILABLE TO PHYSICIANS

The United States Civil Service Commission has announced a new examination for medical officers for filling positions in various specialized fields of medicine, with salaries ranging from $5,940 to $10,800 a year. The positions are principally in the Bureau of Indian Affairs located on reservations west of the Mississippi River and in Alaska. A few positions may be filled in the Fish and Wildlife Service. Applicants must be fully qualified as doctors of medicine, and for most positions must be currently licensed to practice medicine and surgery in a State or Territory of the United States. Appropriate experience is required.

Further information and application forms may be obtained from the U. S. Civil Service Commission, Washington 25, D. C., or from most first- and second-class post offices. Applications will be accepted until further notice by the Board of U. S. Civil Service Examiners, Bureau of Indian Affairs, Department of the Interior, Washington 25, D. C.

NATIONAL SOCIETY FOR MEDICAL RESEARCH

The seventh annual meeting of the National Society for Medical Research was held February 8, 1953, at the Palmer House in Chicago.

Dr. Anton J. Carlson, Professor Emeritus of Physiology at the University of Chicago, was re-elected President. Dr. Andrew C. Ivy, Vice President of the University of Illinois and head of the Chicago Professional Colleges (on leave) was re-elected Secretary-Treasurer. Dr. Maurice Visscher, head of the Department of Physiology, University of Minnesota, was elected Vice President.

The Society voted to give an award in the form of a certificate to Bill Davidson, staff writer for Collier's magazine, for contributions to public health and welfare through scientific articles. A film on the use of animals in medical research is now in production by the Society and will be released shortly.

AMERICAN GOITER ASSOCIATION

The American Goiter Association meeting for 1953, will be held in the Drake Hotel, Chicago, May 7 through 9. The program for the three-day meeting will consist of papers and discussions dealing with goiter and other diseases of the thyroid gland.

COLLEGE OF PHYSICIANS POSTGRADUATE COURSE

Course No. 4—Selected Subjects in Internal Medicine, will be held at Rochester, Minnesota, under the auspices of the Mayo Clinic and Mayo Foundation, March 23-27, 1953.

The directors are Drs. Arlie R. Barnes, W. H. Dearing, Hugh R. Butt, and Edgar V. Allen. Fees are $30 for members and $60 for non-members.

This course is planned to present selected subjects in internal medicine. The talks will include various diseases of metabolism, special talks on gastroenterology, antibiotic therapy, chest diseases, hematologic and cardiovascular disorders. Fundamental physiology as well as clinical and therapeutic aspects of these diseases will be discussed.

Registration must be made through the Executive Offices of the College, E. R. Lovaland, Executive Secretary, 4200 Pine Street, Philadelphia 4, Pennsylvania.

SURGEONS HALL OF FAME

The International College of Surgeons, whose headquarters are housed in a limestone mansion at 1516 Lake Shore Drive, Chicago, recently purchased a mansion next door to house the Hall of Fame. Rebuilding will include the design of individual niches for busts of the great surgeons to be commemorated together with special lighting and bronze plaques detailing their contributions to human welfare.

Those to be honored will be chosen by votes of an electoral college with representatives from every part of the world. Names will be submitted to this group by national organizations or by individual surgeons.

The Board of Trustees for the Hall of Fame includes Morris Fishbein, M.D., Chicago; Henry W. Meyerding, M.D., Rochester, Minnesota; and Alexander Brunschwig, M.D., New York.

AUTORADIOGRAPHY COURSE

An advanced course in autoradiography and three basic courses in radioisotope techniques are course offerings of interest to medical and biological personnel planned this spring and summer by the Special Training Division of the Oak Ridge Institute of Nuclear Studies.

The autoradiography course will be held from June 15-25, and basic courses of four weeks' duration will begin on June 8, July 6, and August 10.

The autoradiography course will be the second to be given at Oak Ridge, an earlier one having been given in the summer of 1951. It is intended for research level personnel using or planning to use this technique in their research.

Lectures, consultations, laboratory demonstrations and discussions will comprise the course. Leaders in the field will be on hand as lecturers and demonstration supervisors.

Subjects to be covered include both the application of the autoradiographic method and the theoretical bases of the method.

Application forms and additional information may be obtained from the Special Training Division, Oak Ridge Institute of Nuclear Studies, P.O. Box 117, Oak Ridge, Tenn.

Knox Gelatine... useful protein supplement in health and disease

Necessary for Nitrogen Balance

Good dietary practice admits of an optimum protein intake of about 100 grams per day with a minimum of not less than 1 gram per kilo of body weight. At least half of the protein should be of first class biologic value, the remainder furnished in a readily assimilable form the 14 or more synthesizable amino acids necessary for nitrogen balance.

Excess Protein Assured

Since large amounts of whole protein are necessary to assure a margin of safety for varied metabolic needs, an excess of protein intake is assured through the use of Knox Gelatine Drink daily. One envelope of Knox Gelatine readily prepared with fruit juice, water or milk, as the patient desires, provides 7 grams of gelatine of which 85 per cent is pure protein.

For Optimal Health

Since protein is not stored in the body, the daily catabolic needs and any extraordinary requirements must be taken care of daily, in order to assure optimal health.

Glycine and Proline Important

Knox Gelatine is a valuable protein supplement, easy to digest and administer as well as being non-allergenic. Knox Gelatine contains important glycine and proline necessary for hemoglobin formation. It has a high specific dynamic action, spares essential amino acids and furnishes amino acids for the continuous dynamic exchange of nitrogen in the tissues.[1]

SUMMER CAMP FOR DIABETIC CHILDREN

A summer camp for diabetic children will be opened for the fifth season under the auspices of The Chicago Diabetes Association, Inc., from July 21, 1953, to August 10, 1953, at Holiday Home, Lake Geneva, Wisconsin.

In addition to the regular personnel of the camp, there will be a staff of dieticians and resident physicians, trained in the care of diabetic children, furnished by The Chicago Diabetes Association.

Boys and girls, ages eight to fourteen years inclusive, will be accepted at a fee of $150.00 (which covers the three-week camping period and transportation from Chicago). Fee reductions may be arranged when considered necessary.

Physicians are requested to notify parents of diabetic children and to supply the names of children who would like to attend camp. Applications may be obtained from, and inquiries should be addressed to: Service Unit, Chicago Diabetes Association, 110 South Dearborn Street, Chicago 3, Illinois.

Limited capacity requires prompt application.

MINNESOTA SOCIETY OF INTERNAL MEDICINE

The spring meeting of the Minnesota Society of Internal Medicine will be held in Minneapolis, Saturday, May 23. Titles and abstracts of papers for the meeting should be sent to Dr. R. S. Ylvisaker, 78 South Ninth Street, Minneapolis 2, on or before April 18.

ASSOCIATION BACKS TV SHOW

The Minnesota State Medical Association is cooperating in the production of a 13-week series of telecasts, put on by the University of Minnesota, through its radio station, KUOM. The telecasts can be viewed on WCCO-TV every Monday morning at 10:00 and will cover various phases of general health problems.

Doctors are urged to watch the show and general comments and suggestions are invited. The entire series is under the supervision and direction of the Association's Committee on Public Health Education.

CENTENNIAL ART AND HOBBY SHOW

By this time the entry blanks and rules and regulation sheets are distributed to all potential exhibitors in the 100th Anniversary Art and Hobby Show of the Minnesota State Medical Association, May 18, 19 and 20. If you have any photography, paintings, drawings, leather craft, wood carving, wood working—anything you have made yourself that you want to show—get your entry blanks in. Deadline for receiving the entry blanks is *April 15*. This will give time to make up a catalogue for the exhibition.

Blanks may be obtained from the Minnesota State Medical Association office, 496 Lowry Medical Arts Building, St. Paul 2, Minnesota, or from chairman James L. Benepe, M.D., 214 Lowry Medical Arts Building, St. Paul 2, Minnesota.

Please follow the rules and regulations in returning your entry blanks and in sending in your entries.

. . . now conveniently located for faster service

You need no longer risk driving through congested traffic to examine new equipment. In this new, modern store you will find complete stocks of instruments and supplies for the physician; model displays of hospital equipment of every type; and a comprehensive range of equipment, apparatus and supplies for the modern medical laboratory. We cordially invite you to visit us at your convenience, or call us for prompt emergency service. Free parking is provided adjacent to building. Telephone: LIncoln 7601.

CONTINUATION COURSES

A continuation course in *Gynecology for Specialists* in that field will be presented by the University of Minnesota on April 16 to 18, 1953. This will be the same program which was originally announced for December, 1952, but which had to be cancelled. The two and a half-day session will be held at the Center for Continuation Study on the University Campus. Subjects to be considered will include endometriosis, culdoscopy as a diagnostic tool, and gynecologic malignancy including the question of carcinoma *in situ*. The course will be presented under the direction of Dr. John L. McKelvey, Professor and Head, Department of Obstetrics and Gynecology, and the remainder of the faculty will include clinical and full-time members of the staff of the University of Minnesota Medical School.

* * *

The University of Minnesota announces a continuation course in *Gastroenterology for General Physicians* which will be held at the Center for Continuation Study from April 27 to 29. All phases of gastrointestinal disease will be covered, and emphasis will be placed on therapy throughout the course. The visiting faculty will include Dr. Chester M. Jones, Clinical Professor of Medicine, Harvard University Medical School, Boston, who will also deliver the Jackson Lecture on the evening of April 28. The course will be presented under the direction of Dr. C. J. Watson, Professor and Director, Department of Medicine, and the remainder of the faculty will include clinical and full-time members of the staff of the University of Minnesota Medical School and the Mayo Foundation.

* * *

The University of Minnesota announces a continuation course in *Surgery for General Physicians* which will be held in the Center for Continuation Study on May 7 to 9, 1952. The visiting faculty for the course will include Dr. Charles Huggins, Professor of Surgery, University of Chicago School of Medicine, who will deliver the annual E. Starr Judd Lecture on Thursday, May 7. The program will be presented under the direction of Dr. O. H. Wangensteen, Professor and Director of Surgery, and the remainder of the faculty will include clinical and full-time members of the staff of the University of Minnesota Medical School and the Mayo Foundation.

* * *

The University of Minnesota will present a continuation course in *Arthritis and Allergy for General Physicians* next May 11-13 at the Center for Continuation Study. Practical management of problems in both of these fields will be emphasized. The visiting faculty will include Dr. Walter S. Burrage, Chief of the Allergy Clinic, Massachusetts General Hospital, Boston. The course will be presented under the direction of Dr. C. J. Watson, Professor and Head, Department of Medicine, and the remainder of the faculty will include members of the clinical and full-time staffs of the University of Minnesota Medical School and the Mayo Foundation.

COUNTY MEDICAL SOCIETIES

President of the *Stearns-Benton Medical Society*, Dr. Joseph B. Gaida, has announced the following committee appointments for the coming year.

Legislative: Drs. John Beuning and Gilman Goehrs, St. Cloud; Dr. A. Zachman, Melrose, and Dr. N. F. Musachio, Foley.

Program: Drs. O. Phares, L. Veranth, and E. Anderson, St. Cloud, and Dr. J. C. Grant, Sauk Centre.

Contact: Drs. C. F. Brigham, Sr., and L. Evans, Sauk Rapids; Dr. H. Reif, St. Cloud, and Dr. L. Kuhlmann, Melrose.

Radio: Dr. F. Baumgartner, Albany; Dr. D. Hoehn, Holdingford; Dr. W. D. Cleaves, Sauk Centre, and Dr. T. Fleming, St. Cloud.

* * *

Officers of the *Washington County Medical Society* re-elected for another term at the January 13 meeting were Dr. Ray G. Johnson, Stillwater, president; Dr. F. M. McCarten, Stillwater, vice president; and Dr. R. E. Carlson, Stillwater, secretary-treasurer. Dr. H. T. Fasbender and Dr. N. J. Kulzer, Hastings, represented the Hastings area which is considering joining the Washington County Society.

* * *

Dr. Walter F. H. Dubbe, New Ulm, was elected president of the *Brown-Redwood-Watonwan County Medical Society*, at the annual meeting, held in January. He succeeds Dr. O. B. Fesenmaier. Other officers are Dr. Albert Fritsche, New Ulm, vice president; Dr. Carl Fritsche, New Ulm, secretary and treasurer; Dr. Rolf Hovde, Winthrop, with Dr. Earl Schroeppel, Winthrop, as alternate delegate to the Minnesota State Medical Association. Three censors elected were Dr. Howard Vogel, New Ulm; Dr. E. J. Wohlrabe, Springfield, and Dr. Adolph Dysterheft, of Gaylord.

Dr. Lyle A. French of the department of Neurosurgery of the University of Minnesota Medical School, spoke to the members on "Low Back Pain and the Intervertebral Disc."

* * *

Dr. John H. Moe, Minneapolis, was elected president of the *Hennepin County Medical Society*, February 2. He will succeed Dr. Claude J. Ehrenberg, October 1. Other officers to assume their duties at the same time are Dr. Willis L. Herbert, first vice president; Dr. Charles A. Aling, second vice president; and Dr. Conrad J. Holmberg, secretary-treasurer. Dr. Thomas J. Kinsella and Dr. Ralph H. Creighton were named to the board of directors.

* * *

Dr. Kenneth H. Peterson, of Hutchinson, was elected president of the *McLeod County Medical Society* at the annual meeting held in January. He succeeds Dr. J. D. Selmo, of Norwood. Dr. Grant Griebie, Brownton, was elected secretary-treasurer.

Woman's Auxiliary

CHAIRMAN NOTES AIDS FOR HEALTH DAYS

Mrs. Lyman Clay, Chairman

These are busy days for all auxiliary members, but possibly members could find a little time to promote a Health Day in their communities.

Where auxiliaries are very small, such projects as promoting a Health Day may seem too great a task for one or two women. But even an afternoon or evening meeting, which can be planned with the help of the P.T.A. or any local group, will result in a very worthwhile program.

Doctors in the area can be of much help with the planning as they are well acquainted with the health needs in the community or what would be of greatest interest to many.

Civilian defense needs promotion and there are many interesting movies, which may be obtained free of charge. Speakers can be obtained from state, regional, or local headquarters.

Safety in the home, on the farm and in everyday living, can be discussed. This will do much to make each individual more alert in the prevention of unnecessary accidents caused by carelessness.

The Minnesota State Department of Health has a very good film library on subjects of medical and dental health, nutrition, poliomyelitis, public health, sanitation, cleanliness and grooming, babies and children, the human body, eye health, and many others. Health and safety films create interest, and visual education is such an easy way to inform an audience on how to meet and solve many problems. There is also free literature available on many of these subjects.

County nurses are always willing to assist, and it would be a tribute to them to let them tell everyone just what a wonderful service they give in protecting the community by their program in health and prevention of diseases.

May 1 is designated as Children's Day throughout the nation. In many schools, the P.T.A. health chairmen plan a special program for all the children. They give prizes for the best posters in each grade, showing good medical and dental health habits.

This is a project that could be done by one auxiliary member alone, if she is the only auxiliary member in her community. The film library has several films that are of interest to the children. Many are cartoons and do much to help promote good health habits that mothers

Crestview C H Hospital Saint Paul

CRESTVIEW

TEACHING FACULTY—ATTENDING STAFF OF COOK COUNTY HOSPITAL

ADDRESS: REGISTRAR, 707 South Wood Street,
Chicago 12, Illinois

sometimes feel they will never make their offspring realize are necessary.

The children would feel greatly honored to have the doctor, the dentist, the town policeman or fireman give them a short talk. The small fry through the teen-ager can be given something they will listen to, look at, and accept. Although much is made over Mother's Day and Father's Day, a Children's Day, even though it is a Health Day, will make them very happy.

The message above is mainly for smaller auxiliaries, but in the larger groups all-day sessions can be planned with less burden to one individual. Help may be obtained from the Minnesota State Department of Health, but they need to be contacted in advance because of the number of places that want their help.

Please remember, a small meeting in a rural community, can be just as successful in alerting interest in happy, healthy living, as in an all-day session involving several counties or a larger town.

The state chairman will help in any way she can to make it easier for anyone. Upon request, program outlines and suggestions, a catalog of health and safety films, health education material are available. The state chairman will also help locate anything needed to make a "Health Day" a success.

RAMSEY COUNTY AIDS NURSE RECRUITMENT

Beginning February 9, and carried through the month of February, a program was presented in each of the fifteen high schools in Saint Paul to inform and interest seniors in the opportunities in the field of nursing, by the Committee on Recruitment of Student Nurses, Fourth District Minnesota Nurses Association.

This program which has been followed for the past four years has been developed with the co-operation of the Directors of Schools of Nursing and the Saint Paul Department of Education.

A panel comprising three student nurses, one of which is from a practical nurse school, one a three-year professional school, and one from a four-year degree school, with a registered nurse as a leader, which tells of the opportunities in nursing is scheduled, through the co-operation of high school principals and counsellors and directors for schools of nursing, for each school.

The Woman's Auxiliary of the Ramsey County Medical Society has done much to support this program and this year is assuming all the responsibility for transportation of panel members to and from the hospitals and the high schools.

All the schools of nursing in the city had Open House March 10, to which high school seniors interested in nursing were invited.

An increasing number of Saint Paul high school graduates are enrolling each year in schools of nursing in Saint Paul.

In Memoriam

WILLIAM HUNTER BARR

Dr. William H. Barr, for many years an outstanding citizen of Wells, Minnesota, died December 27, 1952.

Dr. Barr was born in Carroll, Iowa, December 28, 1879. He attended Drake University and obtained his M.D. degree from the University of Illinois in 1905. After interning at Cherokee State Hospital, Cherokee, Iowa, he opened an office in Wells in 1905.

Dr. Barr had various interests and activities. For eight years, he was a member of the State Board of Health, for twelve years a member of the State Board of Medical Examiners, and was mayor of Wells for four consecutive terms from 1911 on. For years he served as a member of the Wells School Board and was president of the Peoples State Bank.

After serving his community for forty-five years, he was tendered a banquet by the Boy Scouts, Cub Scouts, Campfire Girls and the Blue Birds.

He was a member of the Methodist Church and the Masonic, Elks and Woodmen lodges. He was also a member of the Blue Earth Valley Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Barr is survived by his wife, Stella; two sons, Dr. James Barr, 1st Lt. U. S. Air Force, and William H. Barr, Jr., of Wells; three daughters, Mrs. G. S. Flanagan, Emmons, Minnesota, Mrs. J. M. Anderson, Chicago, and Mrs. K. R. Thorson, Albuquerque, New Mexico.

THEODORE H. DEDOLPH

Dr. Theodore H. Dedolph of Braham, Minnesota, died unexpectedly December 22, 1952 at Veterans Hospital, St. Cloud. He had been a patient there since 1941.

Dr. Dedolph was born in Saint Paul, March 10, 1889. He attended Mechanic Arts High School in Saint Paul and received his medical degree from the University of Minnesota in 1912. He began practice in Braham that same year as an associate of the late Dr. Charles Swenson.

In 1918, he enlisted in the Medical Corps and served a year in France during World War I. Following his discharge from service, he went to Oakes, North Dakota, but in 1922 returned to Braham, where he practiced until his retirement.

In 1922 Dr. Dedolph was married to Erica Erickson of Braham, who survives him, together with a son, Dr. Theodore Dedolph, Jr. The late Dr. Karl Dedolph of Saint Paul was a brother. Another brother, Frederick, of Fullerton, California, and a sister, Mrs. Edwin A. Hendricks, of Minneapolis, also survive.

Dr. Dedolph had been an affiliate member of the Minnesota State Medical Association since his retirement. He was a Mason and life member of the Zuhrah Temple, Minneapolis, and a member of the Legion of Honor of the Shrine.

C. F. HOLST

Dr. C. F. Holst, a practicing physician in Little Falls, Minnesota, from 1903 to 1947, died January 12, 1953 at the age of seventy-eight.

Dr. Holst was born in Goodhue County, Minnesota, February 8, 1874. He obtained his medical degree at the University of Minnesota in 1901 and attended the Chicago Postgraduate School and the Chicago Eye and Ear Clinic in Chicago.

After practicing at Hendricks, Minnesota, from 1901 to 1903, he located at Little Falls, where he was associated with his brother, Dr. J. B. Holst.

During World War I, Dr. Holst served in the medical corps of the army.

In June, 1920, he was married to Regina Werner of Breckenridge. His wife and two daughters, Mrs. H. R. Carney of Edina and Mrs. J. W. Cullen of Cleveland, Ohio, survive him. A brother, Dr. John B. Holst of Little Falls, also survives him.

Dr. Holst was a member of the Upper Mississippi Medical Society, the Minnesota State Medical Association and the American Medical Association.

LINWOOD D. KEYSER

Dr. Linwood D. Keyser, former fellow in pathology of the Mayo Foundation, died of chronic nephritis and rheumatic heart disease on October 12, 1952.

Dr. Keyser was born on September 26, 1893, at Victoria, Texas. He received the degree of B.A. in 1914 from the University of Virginia, of M.D. in 1918 from Johns Hopkins University, and of M.S. in Pathology in 1921 from the University of Minnesota. He was a first lieutenant in the Medical Reserve Corps of the United States Army during World War I. He was an intern at Johns Hopkins University Hospital for one year, was assistant resident surgeon at the Peter Bent Brigham Hospital, Boston, for six months, and was resident surgeon at the New York Post-Graduate Hospital for six months. He entered the Mayo Foundation as a fellow in pathology in September, 1920; his services included pathology, experimental surgery, general surgery and orthopedic surgery, following which he left the Mayo Foundation in July, 1923. He practiced general and urologic surgery at Roanoke, Virginia, where he was attending surgeon and surgical pathologist at the Roanoke Hospital and consultant surgeon to Gill Memorial and Burrell Memorial hospitals.

Dr. Keyser was certified as specialist in urology by the American Board of Urology, was a fellow of the American College of Surgeons and a member of the American Medical Association, the American Urological Association, the Johns Hopkins Surgical Society, the American Association for the Advancement of Science, the Roanoke Academy of Medicine, the Tri-State Medical Society of Virginia and the Carolinas, the Southern

Medical Association, the Southwest Virginia Medical Society, the Southeastern Surgical Congress, the American Association of Genito-Urinary Surgeons, the Alumni Association of the Mayo Foundation and Sigma Xi.

CARL L. LARSEN

Dr. Carl L. Larsen, well known eye, ear, nose and throat specialist in Saint Paul, died suddenly of a heart attack on January 29, 1953, at his home.

Dr. Larsen was born at Menomonie, Wisconsin, April 27, 1881. He graduated from Hamline medical school in 1904 and interned at the City and County (Ancker) Hospital in Saint Paul in 1904-05. He practiced at Buffalo, Minnesota, from 1905 until 1910 and then took postgraduate work in 1910-11. Later, in 1921 and again in 1927, he took further postgraduate work in London.

He was president of the Ramsey County Medical Society in 1924, the year the American College of Physicians met in Saint Paul. He was a member of Phi Rho Sigma, undergraduate medical society, the Rotary Club, the Town and Country Club and the Athletic Club.

Dr. Larson lost his wife a few years ago. He is survived by his daughter, Mrs. Gilbert Brown, and his son, Frank E., of North Hollywood.

Dr. Larsen had an extensive practice and a host of friends. Besides being an able specialist and a member of the American College of Surgeons, he played golf until a few years ago and was a bridge enthusiast.

JOHN SILLIMAN MACNIE

Dr. John S. Macnie, well-known specialist in eye, ear, nose and throat diseases in Minneapolis for many years, died January 30, 1953. He was seventy-eight years of age.

Dr. Macnie was born at Newburgh, New York, May 21, 1874. He received a B.A. degree at the University of North Dakota, Grand Forks, in 1893 and his M.D. degree from the College of Physicians and Surgeons at Columbia, New York, in 1896.

After taking postgraduate work in London and Vienna, he returned to Minneapolis in 1904 and joined the medical staff of the University of Minnesota. He retired as associate professor of Ophthalmology from the University staff in 1944.

Mrs. Macnie died four years ago. Dr. Macnie is survived by two sons, John P., of New York, and Robert O., of Minneapolis.

Dr. Macnie was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

MANFORD O. OPPEGAARD

Dr. M. O. Oppegaard, an outstanding physician in the state, died January 22, 1952.

Dr. Oppegaard was a founder of the Northwestern Clinic at Crookston and as its president was largely responsible for its growth from a staff of two physicians

---

and one dentist to a personnel of twelve physicians and twenty-eight lay members. The clinic was established in 1920 when Dr. Oppegaard came to Crookston.

Dr. Oppegaard was born September 8, 1885, at Taylor, Wisconsin. He obtained a B.S. degree from the University of Minnesota in 1908 and his M.D. degree in 1910. After interning at St. Luke's Hospital in Saint Paul, he took postgraduate work at the Polyclinic in Chicago, at the New York Postgraduate Hospital, and at the Massachusetts General Hospital in Boston.

Before establishing the Northwestern Clinic in 1920, he practiced in New London, Minnesota, for seven years and in Minneapolis for three years.

Dr. Oppegaard was active in medical organizations, having been president and secretary of both the Red River Valley Medical Society and the Northern Minnesota Medical Association. He was also interested in the Elks, the Shrine and the Rotary Club. From 1946 to 1952, he served as mayor of Crookston following his retirement from practice.

Surviving are his widow, a son, Manford M., of Winston-Salem, North Carolina; a daughter, Mrs. George Leichsenring of Oak Ridge, Tennessee, and two brothers, Dr. C. L. Oppegaard of Crookston and M. M. Oppegaard of Grand Forks, North Dakota. A sister, Mrs. O. E. Locken of Minneapolis, also survives him.

Dr. Oppegaard was a member of Sigma Xi and Alpha Omega Alpha scientific societies and was for many years a member of the Minnesota State Medical Association and the American Medical Association.

JOHN E. PLUNKETT

Dr. John E. Plunkett, former fellow in medicine of the Mayo Foundation, died of cardiac insufficiency on January 11, 1953, in Ottawa, Ontario, Canada.

Dr. Plunkett was born on April 17, 1900, at Peterborough, Ontario. He received the degree of Phm.B. in 1922 from the University of Toronto and the degree of M.D., C.M. in 1930 from Queen's University, Kingston, Ontario. He was an intern at the Ottawa Civic Hospital in Ottawa in 1930 and 1931 and resident physician there in 1931 and 1932. Dr. Plunkett entered the Mayo Foundation as a fellow in medicine on July 1, 1932, and left April 1, 1935, at which time he returned to Ottawa to engage in the practice of general medicine. He was an assistant professor of clinical medicine at Queen's University and was on the staff of the Ottawa Civic Hospital until the time of his death.

Since 1945, Dr. Plunkett had been an honorary secretary of the Royal College of Physicians and Surgeons of Canada. He was an officer of the Militia Reserve of Canada and a member of the Montreal Medical-Chirurgical Association, the New York Academy of Sciences, the Ontario Medical Association, the American Heart Association and the Alumni Association of the Mayo Foundation.

Of General Interest

Two brothers, **Dr. George R. Smith,** of Hutchinson, and **Dr. Ralph Smith,** of Minneapolis, were called to military service in January within a week of one another.

Dr. George R. Smith, a graduate of the University of Minnesota Medical School, 1946, for the past three and one-half years has been in practice in Hutchinson with **Dr. E. W. Lippmann.** Dr. Smith reported to Gunter Air Force Base, January 15, for service with the Air Force.

Dr. Ralph Smith, a graduate of the University of Minnesota Medical School, 1945, served two years with the navy after completing medical school. He did research work at the University of Minnesota until 1951, and was in charge of medicine at Ancker Hospital during 1951 to 1952. Recently he has been on the staff of the Veterans Hospital at Ft. Snelling and the University of Minnesota. Dr. Smith reported to Jamaica, New York, January 7, where he will be in charge of Naval Research at St. Albans Hospital.

Dr. Dan W. Heubert, Halstead, Kansas, filled the vacancy in Hutchinson left by Dr. George R. Smith. Dr. Heubert recently completed a tour of duty with the Air Force.

* * *

Dr. I. L. Oliver, accompanied by Mrs. Oliver, left Graceville in January for a two-month trip through several South American countries. Dr. Oliver is one of 200 members of the American College of Surgeons who attended the inter-American session of the college, held in Sao Paulo, Brazil, February 13-18.

* * *

Dr. W. E. Hall, of Maple Lake, has been selected as one of the civil defense directors and physicians of Wright County.

* * *

Dr. Nelson J. Bradley, superintendent of the Willmar State Hospital, was a guest panelist on a KSTP-TV show Sunday, January 11. Dr. Bradley and four other panel members (Rev. Forrest Richeson, of Minneapolis; James Otis, Saint Paul municipal judge, and Lynn Carroll, managing director of the Hazeldon Foundation) discussed the problems of alcoholics. The program was the first in a series of such programs and was entitled, "The Hidden Man."

* * *

A bronze plaque in memory of **Dr. O. W. Anderson,** former Luverne physician, was given to the Luverne Hospital by Alan C. McIntosh, editor and publisher of the *Rock County Star-Herald,* recently.

* * *

Dr. Richard L. Varco, professor of surgery at the University of Minnesota, spoke to a joint group of physicians and nurses, January 8, at the first of eight medical sessions sponsored by the Blue Earth Valley Medical Society, the Southern Dental District, Fifth District, Minnesota Nurses Association, and District two of the Minnesota Department of Health. Dr. Varco's topic for the evening was "Lung Cancer."

* * *

Dr. Henry P. Staub has reopened his office at 2300 Central Avenue, Minneapolis, after serving twenty-two months in the armed forces. Most of Dr. Staub's military service was in Germany.

* * *

Dr. A. B. Hayles, of the department of pediatrics at the Mayo Clinic, addressed the Tri-County Medical Society at an evening meeting, January 14. Dr. Hayles spoke on "Problems of Endocrinology in Childhood."

* * *

Dr. Wallace P. Ritchie, Saint Paul, spoke at the dedication ceremonies of the Macalester College new Winton Health Center, February 8. Dr. Ritchie is a Macalester trustee.

* * *

Dr. Vincent Paciotti, formerly of Perham, was released from military service, February 1, and will live in Minneapolis. Dr. Paciotti recently returned from Japan and has accepted a residency in radiology at the University of Minnesota Hospitals.

* * *

Dr. Frank Farley, Cincinnati, Ohio, began practice in Hibbing with the Adams Clinic in January.

* * *

Dr. D. P. Anderson, Austin, spoke to the members of the Austin Rotary Club at the February meeting on "What the Patient Should Know."

* * *

Dr. McLemore Bouchelle, formerly resident surgeon at Columbia Presbyterian Medical Center, New York, New York, joined the staff of the East Range Clinic at Virginia, January 20. Dr. Bouchelle was graduated from the Harvard Medical School in 1943. He interned at Columbia Prebyterian Medical Center in New York and then served in the army for twenty-seven months in the American and Pacific theatres.

Dr. Bouchelle's appointment to the staff brings the total number of doctors at the clinic to four. The other doctors are **Dr. J. Armond Malmstrom, Dr. Paul Reed,** and **Dr. John Indihar.**

* * *

Dr. Joseph. M. Ryan, chief of medicine at St. Joseph's Hospital, Saint Paul, took a month's course in techniques of using radioscopes at the Oak Ridge Institute of Nuclear Studies, in January.

* * *

Dr. Don Hoganson, of Bemidji, recently returned from medical duty with the army in Korea, presented a front line picture to members of the Headwaters Shrine Club, at the February meeting. Dr. Hoganson showed slides of pictures he took while on duty in front line action and during the Koje Island

When Is A Dollar A Dollar?

It is quite common today to hear about a "50c dollar"—a dollar that buys what only 50c would buy in the past.

Many people, however, have not heard about the "60c dollar"—a dollar of investment income that shrinks to 60c after income taxes are paid.

Two men in similar financial circumstances ($12,000 taxable income bracket for example) are each receiving income from investments:

One man receives a "60c dollar."

The other receives a "$1.00 dollar."

WHY?

Income from corporate bonds and stocks, government bonds, contracts for deed, mortgages and most other investments is subject to our present Federal Income tax.

Income from Municipal Bonds is exempt from such tax.

ARE YOU INTERESTED IN RECEIVING A "$1.00 DOLLAR" FROM YOUR INVESTMENTS?

Write or call for descriptive circulars of municipal bonds we are currently offering.

* * *

Dr. F. L. Bregel, of St. James, has closed his office there and accepted a position with the Veterans Administration in Saint Paul. Dr. Bregel started working with the Veterans Administration, January 1.

* * *

Dr. Frederick J. Kottke, head of the department of physical medicine at the University of Minnesota Hospitals, directed a one-day conference on poliomyelitis at the University Center for Continuation Study, January 15. **Dr. Gaylord W. Anderson,** director of the School of Public Health at the University, outlined recent trends in immunization against poliomyelitis.

* * *

Dr. Lewis Thomas, professor of pediatrics and medicine at the University of Minnesota Medical School, was awarded $1,900 by the Rockefeller Foundation, January 22. The fund was awarded for study in Europe. Dr. Thomas will leave early in April for a two-month visit to laboratories in Great Britain and on the Continent where work on rheumatic fever and related problems is being carried on.

* * *

Dr. Lewis Hanson, of Frost, spoke on poliomyelitis at the January meeting of the Frost Parent Teachers Association.

Dr. Lloyd C. Gilman, of Willmar, left January 15, for Madison, Wisconsin, where he will spend a year as a surgical assistant to Dr. Arnold Jackson of the Jackson Clinic. Dr. Gilman has been in practice since 1938 when he was graduated from the University of Minnesota Medical School—he first located in Osceola, Wisconsin, then at Atwater from 1938 to 1941, until he was called into the armed forces. After four and a half years of army medical corps service, Dr. Gilman began practice in Willmar. In 1949 he became associated with the Lakeland Medical Center group of doctors which was established that year. Dr. Gilman plans to return to Willmar after one year's stay in Madison.

* * *

Dr. C. R. Openshaw and **Dr. N. W. McQuay** of the Mayo Foundation, recently joined the staff of the Nopeming Sanatorium where they will be affiliated for several months.

* * *

Dr. Ivan D. Baronofsky, associate professor of the University of Minnesota Medical School, was a guest consultant at the first of two clinical conferences for physicians of the Wright County Medical Society on cancer and heart disease at Cokato in January. These pathological conferences (the second to be held April 7) are sponsored by the Minnesota Department of Medicine of the University of Minnesota, the Minnesota Medical Association, the Minnesota Cancer Society, and the Minnesota Heart Association.

* * *

A $55,000 remodeling and construction program will begin on **Mineral Springs Sanatorium,** Cannon Falls, this year. Eight counties have participated in providing funds for the work.

* * *

Dr. Mancel T. Mitchell was named the new president of the Minneapolis War Memorial Blood Bank, in January. **Dr. Karl S. Klicka,** Hadlai Hull, and **Dr. R. F. McGandy** were elected vice presidents by the board of directors.

* * *

The new Heisler Clinic at 6224 Lyndale Avenue S., Richfield, was completed and opened in late January. Heading the clinic is **Dr. John J. Heisler.** Staff members include **Dr. James Arms, Dr. Alex Ratelle,** Dr. Les Nelson (dentist), and Neil Johnson (pharmacist). Plans for the building were drawn up by Dr. Heisler's brother, Robert P. Heisler.

* * *

Dr. Harold S. Diehl, dean of medical sciences at the University of Minnesota, took part in a panel discussion of the impact of national defense on medical education at the Forty-ninth Annual Congress on Medical Education, held in Chicago, February 8-10.

* * *

Dr. A. B. Baker, head of the neurology department at the University of Minnesota Medical School, addressed the second annual meeting of the Minnesota chapter of the National Mutiple Sclerosis Society, held January 21, at St. Luke's Hospital in Duluth. Dr. Baker spoke on new trends in diagnosis and treatment of multiple sclerosis.

* * *

Dr. Leo G. Rigler, professor of radiology at the University of Minnesota, has been named to a team of fifteen medical scientists who went to India in February to advise doctors there on the latest medical knowledge. Dr. Rigler, who previously went on a similar mission to Japan, is one of five Americans on the team. Others are Dr. Joseph C. Aub and Dr. John E. Gordon, of Harvard; Dr. Samuel Z. Levine, Cornell University, and Dr. Stuart C. Cullen, University of Iowa. The team was sent at the request of the Indian Health Ministry and jointly sponsored by the United Nations World Health Organization and the Unitarian Service Committees.

* * *

Dr. Howard R. Hartman, Rochester, who recently retired as senior consultant of the Mayo Clinic's clinical section, became a consulting physician to the Chrysler Corporation in January.

* * *

Dr. Mary C. Ghostley, director of Lake Julia Sanatorium at Puposky for twenty-three years, was honored at a surprise banquet, January 14, celebrating her retirement. Dr. Ghostley, a graduate of the University of Minnesota Medical School in 1909, established her first practice in Blackduck but soon moved to International Falls where she practiced for twenty years. "Dr. Mary," as she is known, retired because Lake Julia was closed in January. The number of tuberculosis cases has been cut to a point where the smaller institutions not equipped for some of the modern treatments of the disease, are being closed. Lake Julia Sanatorium, after thirty-six years of service to its three-county (later four) area, was the fifth of the fourteen small sanatoriums in the state to close.

* * *

Dr. J. K. Butler, Cloquet, was the featured speaker at the organizational meeting of the county committee of the American Heart Association held at the Northeastern Hotel at Cloquet, January 15. The fund drive for the Heart Association opened February 1.

* * *

Dr. John Indihar, Virginia, was in charge of preschool clinics held January 20, at Mountain Iron School, Parkville School and the West Virginia School. Mrs. Lillian Fuller, school nurse, made arrangements for the clinics.

* * *

The January issue of the *Mississippi Valley Medical Journal* (Quincy, Ill.) contains all the papers read at the recent annual meeting of the American Medical Writers' Association. There are papers by **Dr. Walter C. Alvarez,** formerly of Minnesota, and Prof. Theodore Peterson, University of Illinois, Prof. J. Linwood Cutler, University of Missouri, Dr. Harold Swanberg, Editor, *Mississippi Valley Medical Journal,* and Dr. W. W. Bauer, Editor of *Today's Health.* The first four comprise an interesting Symposium on Medical Writing conducted at the St. Louis meeting. The two winning essays in the twelfth annual essay

Dr. and Mrs. Robert D. Thielen and their daughters, Janet and Judith, of St. Michael, recently returned from a month's trip through Florida and a cruise to the West Indies. They sailed December 22 on the SS Nuevo Dominicano for Nassau Dominican Republic and Haiti.

* * *

Dr. J. L. Bader, of Slayton, attended the short course in anesthesiology at the University of Minnesota Continuation Center, in January.

* * *

Two specialists who recently joined the St. Louis Park Medical Center are **Dr. Robert L. Koller** (eye, ear, nose and throat), of Edina, and **Dr. Titus P. Bellville** (gynecology and obstetrics) of Minneapolis. Dr. Bellville replaces **Dr. Alex Barno** who was recalled to active duty with the U.S. Navy.

Dr. R. Gordon Douglas, Chief of the New York Lying-In Hospital, was a recent house guest of **Dr. and Mrs. William B. Stromme,** of Minneapolis.

* * *

Dr. James Rogers Fox of the University of Minnesota Medical School faculty, spoke on "Inside the British Health Plan," at a luncheon meeting of the Ramsey County Medical auxiliary, January 26.

* * *

Dr. C. W. Mayo, of Rochester, was re-appointed as a member of the University of Minnesota Board of Regents, in January. Dr. Mayo was appointed a regent of the University in February, 1951, after the resignation of Mr. A. J. Lobb, of Rochester, from the post.

* * *

Dr. C. H. Sherman, of Bayport, and **Dr. W. C. Bernstein,** formerly of Stillwater, joined the staff of the new Hudson Memorial Hospital, Hudson, Wisconsin, in January.

* * *

Dr. Winchell M. Craig, Mayo Clinic neurosurgeon and professor of neurosurgery in the Mayo Foundation, was recently elected president of the Association of Military Surgeons of the United States.

* * *

Dr. Donald W. Hastings, Professor and Head of the Department of Psychiatry and Neurology, University of Minnesota Medical School, attended a meeting in Paris, February 23-25, under the auspices of The Advisory Group for Aeronautical Research and Development of the NATO. He is chairman of the Aero-Medical Panel of the United States Air Force Scientific Advisory Board and will present a paper on Psychiatric Selection of combat flying personnel.

* * *

Dr. A. C. Aufderheide, of Minneapolis, spoke at the Inter-Urban Academy of Medicine meeting, held January 21 at the Spalding Hotel, Duluth.

* * *

Dr. Henry F. Helmholz, Rochester, chairman of the national Parent Teachers Association's health committee, announced that the national Congress of Parents and Teachers is asking its local groups to promote fluoridation of community water supplies.

* * *

Dr. George Heine, of the Little Falls Clinic, was recalled to active duty with the Navy, in January. He reported to Coronado, California, Navy amphibious base, February 4. **Drs. G. M. A. Fortier** and **Milo Hansen** will take care of Dr. Heine's practice in his absence.

* * *

Dr. C. F. Burnett, of the Northwest Clinic of Crookston, was guest speaker January 30, at the Eldred Parent Teachers Association meeting. Dr. Burnett spoke on polio, its treatment and prevention.

* * *

Dr. Robert P. Pierce, formerly of Renville, began practice in Danube, in January.

Dr. J. T. Saidy left Rochester recently to begin private practice at San Mateo, California. Dr. Saidy completed his fellowship in the Mayo Foundation in January.

* * *

Dr. O. W. Roberts, of Owatonna, spoke on "Heart Disease" to a group in Medford, where the first of four programs in Steele County, under the auspices of the Minnesota Heart Fund, was held.

* * *

Dr. E. V. Allen, consultant in medicine at the Mayo Clinic, and **Dr. John Kirklin,** consultant in surgery, were featured speakers at the quarterly dinner for new fellows of the Mayo Foundation, held January 29, in Balfour Hall of the Mayo Foundation House. The evening's program included singing by the Fellows chorus directed by **Dr. Richard Sholl** accompanied by **Dr. William Parsons. Dr. Clayton Klakeg,** vice president of the Fellows Association, was master of ceremonies.

* * *

Dr. Wallace E. Herrell, a member of the permanent staff of the Mayo Clinic since 1938 and noted for his early work with penicillin, will leave Rochester in August to enter the section of medicine in the Lexington Clinic, Lexington, Kentucky.

Dr. Herrell began his research on penicillin in 1941, after Dr. H. W. Flory of Oxford, England, one of the first to purify penicillin for clinical use, visited the clinic. With **Dr. Luther Thompson** and **Dr. E. N. Cook,** Dr. Herrell wrote the first clinical report on the successful use of penicillin in the treatment of gonorrhea. Dr. Herrell's particular fields have been tissue regeneration, chemotherapy and experimental and clinical studies of antibiotic substances.

* * *

Dr. William J. Lick has opened an office at 244 Lowry Medical Arts Building, Saint Paul, for the practice of Internal Medicine. He is a Diplomate of The American Board of Internal Medicine.

* * *

Richard L. Engwall, of Winthrop, was selected as the recipient of the first Minnesota State Medical Association rural medical student scholarship. This consists of $1,000 a year for four years and in return the recipient has promised to practice medicine in a Minnesota town of 5,000 or less. The presentation of the scholarship was made by **Dr. F. J. Elias,** chairman of the Scholarship Selection Committee, to Mr. Engwall at the annual county officers meeting sponsored by the MSMA which was held at the Saint Paul Hotel, January 17, 1953. It is felt that this scholarship and additional ones planned for the near future constitute one way in which the profession of the state can take part in a positive fashion in helping to secure more physicians for rural areas.

* * *

Dr. Ivan Baronofsky, director of surgical postgraduate study at Ancker Hospital, Saint Paul, addressed a group of private duty nurses on thoracic surgery, February 3. The occasion was a one-day conference on nursing poliomyelitis, chest surgery

* * *

Dr. L. E. Steiner, of Albert Lea, spoke to the local Rotary Club, February 6, explaining functions of the American Medical Association, the state medical group and the county organizations.

* * *

Dr. Charles M. Jessico, Duluth, spoke on "Psychiatry from Catholic Doctors' Viewpoint," at a breakfast meeting of the Holy Name Society of Our Lady of the Rosary Catholic Parish, Sunday, February 8.

* * *

Dr. R. H. Wilson, of Winona, was called upon to attend Miss America (Miss Neva Jane Langley) when she became ill at Winona during the Winona Winter Carnival.

* * *

Dr. Edward Banner, of the Mayo Clinic, spoke to the guests at the annual father and son fellowship dinner and program of the First Methodist Church, Rochester, February 3. Dr. Banner spoke on developments in outer space travel, man-made satellites, et cetera.

* * *

Dr. Herb L. Huffington, of Montevideo, plans to begin practice in Waterville about April 1.

* * *

Dr. Helen Fukashima, instructor at Miller Hospital, Saint Paul, served as the choreographer for Bethany College's production of the operetta "The Mikado," to be given at Mankato. Dr. Fukashima, although born in Minneapolis, moved to Japan as a small girl and lived there until 1948. She was graduated from Tokyo's Women's Medical School.

* * *

Dr. Malcolm M. Hargraves, of the Mayo Clinic, addressed a group of farmers, businessmen and their wives attending the annual dinner meeting of the Steele County Soil Conservation District, held in Blooming Prairie in January. Dr. Hargraves talked on the rise and fall of civilizations and their relation to agriculture.

* * *

Dr. Howard Bosland, of Willmar, spoke at the West Central Minnesota Dental Study Club, held at the Lakeland Hotel in Willmar, February 5. Dr. Bosland's subject was "The Dentist's Health."

* * *

Poliomyelitis, wonder drugs, and the plight of the aging, were the special topics under discussion during the tenth annual Community Health Day in the Radisson Hotel, February 6. Speakers and panel members from the medical profession included **Dr. Gaylord Anderson,** Director of the University of Minnesota School of Public Health; **Dr. Wesley Spink,** professor of medicine at the University of Minnesota, and **Dr. Reynold A. Jensen,** Hopkins.

The women's auxiliaries to the Hennepin County Medical and Minneapolis District Dental Societies sponsored the event.

Dr. Leonard B. Moyer, formerly of Lake Preston, South Dakota, began practice with **Dr. G. F. Engstrom** in Belgrade Community Hospital, in February. Dr. Moyer has served for four years as surgeon with the United States Public Health Service and two years with the Army Medical Corp.

* * *

Dr. George E. Williams, of the Rochester-Olmsted County public health center, showed and discussed the film, "Fears of Children," at a meeting of the Northrop Mother's Club of Rochester.

* * *

Dr. Hamline Mattson, Minneapolis, officiated as president of the Minneapolis Surgical Society at the thirty-first annual Founders' Day banquet at the Minneapolis Club, February 4. Guest speaker was Dr. Karl Myer, chairman of the division of surgery at Cook County Hospital, Chicago.

* * *

Dr. Arthur C. Kerkhof, and **Dr. Carleton B. Chapman,** associate professors of medicine at the University of Minnesota, spoke at a Blue Earth Valley Medical Society Seminar group, February 6. This was the fourth seminar session; the seminars are sponsored by the Blue Earth Valley Medical Society, Southern Dental District, Minnesota Nurses Association, District 5, and the Minnesota Department of Health, District 2.

Dr. Victor Johnson, director of the Mayo Foundation, participated in the program of the forty-ninth annual Congress on Medical Education and Licensure, held in Chicago, February 8 to 10.

* * *

The Dr. George J. Tweedy Memorial Fund, established by friends and the family of the physician following his death July 20, 1952, has been used to purchase equipment for Winona General Hospital. Dr. Tweedy spent fifty-nine years in medical practice in the Winona vicinity. His two sons, **Dr. Robert Tweedy** and **Dr. John Tweedy,** have offices in the city and are members of the medical staff of the hospital.

* * *

Dr. Louis A. Buie, of Rochester, senior consultant in the Section of Proctology of the Mayo Clinic, has been asked to serve as a member of the National Foundation for Infantile Paralysis, Inc. The term runs from January 1, 1953, to December 31, 1955. Dr. Buie has been a member of the Committee on Professional Education and Publications of the national poliomyelitis group.

* * *

Dr. C. W. Moberg, of Detroit Lakes, attended a two-week postgraduate course in surgery, in February, held at the Cook County Hospital, Chicago.

* * *

Dr. Charles W. Mayo and **Dr. Raymond J. Jackman,** of the Mayo Clinic, participated in the first inter-American session of the American College of Surgeons, held February 9-12, at Sao Paulo, Brazil.

* * *

Dr. P. J. Schneider, of Adams, held open house in his new office building, in February.

* * *

Dr. S. G. Knight, of Randall, although officially retired three years ago after forty years of practice in the community, still carries on a limited practice from a small office in his home. The eighty-three-year-old doctor came to Randall in 1910 from Ontario, Canada. Dr. Knight was a classmate of Dr. Allan R. DaFoe of Callander, Ontario—the doctor who delivered the Dionne quintuplets of Canada—and has quadruplets in his own family. The Hargreave quadruplets of Canada were born to a grandniece of Dr. Knight.

* * *

Two new doctors, **Dr. J. Roger Nickerson,** Heron Lake, and **Dr. Neil Nickerson,** Thief River Falls, joined **Dr. R. C. Hunt** and **Dr. Robert S. Hunt** in their practice in the Fairmont Clinic, in late February.

* * *

Dr. D. R. Philp, of Windom, was entertained at a farewell dinner given by the nursing staff of the Windom Hospital, February 9. Dr. Philp left in February for a tour of active duty with the armed forces. Among community members attending the dinner were **Dr. H. P. Basinger,** Windom, and **Dr. Robert Sawtell,** of Jeffers.

Dr. Percy T. Watson, Minnesota Department of Health, has retired after serving the people of this state for seventeen years. The preceding twenty-seven years Dr. Watson spent doing public health work in China. One of his outstanding achievements during his missionary physician work was the organization of expeditions to stop recurrent epidemics of bubonic and pneumonic plague.

Dr. Watson returned to the United States in 1934 and a year later he joined the health department. He received his medical degree from Johns Hopkins in 1907 and his M.P.H. from Harvard. Dr. Watson did postgraduate work at the Mayo Clinic. Two of his children are physicians—Dr. R. Janet Watson, of Brooklyn, New York, and **Dr. Theodore Watson,** of Saint Paul.

* * *

Dr. Henry E. Michelson, of Minneapolis, delivered two professorial lectures before the New York University Postgraduate Medical School in New York, January 29 and 30. The subjects of the lectures were the Lupus Erythematosus Problem and the Pathogenesis of Sarcoidosis.

* * *

Dr. Merrill D. Chesler, of Minneapolis, was the principal speaker at the meeting of the Renville County Medical Society, held at Olivia, February 17. The title of his talk was "The Use of Skin Grafts and Flaps."

HOSPITAL NEWS

Dr. V. D. Thysell of Hawley, was elected president of the medical staff of **St. Ansgar Hospital** at Moorhead, at the annual meeting in January. Dr. E. W. Humphrey, Jr., Moorhead, was elected vice president, and Dr. Carl Simonson, re-elected secretary. Dr. James Oliver was the retiring president. Four doctors were cited for attendance records at the monthly meetings, including Dr. Simonson, Dr. H. G. Rice, Dr. Thysell, and Dr. Oliver.

* * *

Dr. Leonard A. Lang has been elected chief of staff at **St. Mary's Hospital,** Minneapolis, succeeding Dr. Leo Culligan. Dr. Horatio Sweetser was elected vice president and Dr. James Trow, secretary-treasurer. The medical advisory committee includes the officers and Dr. T. J. Kinsella, Dr. Maurice McInerny, and Dr. Willard D. White.

* * *

Dr. Olga S. Hansen Litzenberg, Minneapolis, was elected chief of staff of **Eitel Hospital,** Minneapolis, at the annual meeting in January. Dr. G. T. Schimelpfenig was elected assistant chief of staff, and Dr. O. L. Zahrendt, secretary-treasurer. Honorary life memberships to the staff were presented to Drs. S. Marx White, William H. Condit, Arthur C. Strachauer, Alfred T. Baker, Hugh J. Tunstead, and Henry L. Ulrich.

Boyer, Jr., the retiring chief. Dr. Ralph Eckman was elected staff secretary. Dr. Stuart C. Cullen, professor of anesthesiology at the University of Iowa, was the guest speaker for the evening.

BLUE CROSS-BLUE SHIELD

In a recent analysis of Blue Shield claims, it was found that twelve claims paid by Blue Shield were covered under the Workmen's Compensation laws and consequently were not eligible for Blue Shield benefits. It was apparent from the review that Blue Shield had paid these claims because the space on the Medical Service Report requesting information on Workmen's Compensation coverage had not been marked properly. Other reviews have shown similar problems arising from improper or inaccurate reporting to questions on the Blue Shield claim blank. Principally the difficulties concern the failure to include the patient's birth date, the dates services were rendered, the charges made for the services, the appropriate annual income date, the signature of the attending doctor, and the date the condition for which care was rendered first existed or was known to exist. Omission of information such as listed in the foregoing statement creates additional administrative costs and also delays the action and payment of a claim over a longer period of time than is necessary.

The Medical Service Report form or claim blank which is furnished by Minnesota Blue Shield is worded in such a manner as to reduce to a minimum the time and effort required for its proper completion. Most of the items on the form merely require a check mark, while the remainder needs only a few words or figures. Constant study is being made for new ways to simplify and improve this claim form for the convenience of the profession and the subscriber.

The birth date of the patient, as previously stated, is frequently omitted by both doctor and subscriber, but it is of extreme importance in the correct processing of Blue Shield claims. For example, it is not possible to pay some claims such as those for hernia unless the age of the patient is known, due to the fact that operations for hernias carry a smaller fee for children under ten years of age. Conversely, for tendon repairs in children under five years of age, the payments are double those for persons of more advanced years. Other considerations such as the validity of a dependent's contract are related to the subscriber's birth date.

Annual income of the subscriber influences the amount and method of payment of a claim. The exact amount of the annual income is not required. It is only necessary to ask the patient if his income is above or below the Blue Shield service benefit income level, and check the appropriate space on the Medical Service Report. After the payment of claims, letters are often received from subscribers inquiring why an additional bill was sent to them by the doctor when they were entitled to the benefits of unlimited subscribers. Review of the files in such cases invariably indicated that there has been a failure to check the income level.

A substantial number of incorrect payments are caused by inaccuracies and incompleteness in that portion of the Medical Service Report set aside for stating the services rendered. For instance, when a gall bladder is removed with exploration of the common duct, the Medical Service Report most frequently contains only the fact that the operation was a cholecystectomy. The result is that $125 is paid whereas $150 should have been paid. Or, when a hysterectomy is performed, it is essential that Blue Shield be informed whether the surgery was a total or only a sub-total hysterectomy since the Schedule carries a different fee for each. Similarly with all services, complete description is necessary for proper payment, and the dates the services were rendered as well as the doctor's charges help in paying claims properly.

Finally, it is necessary that the doctor's name and

address as well as his signature be furnished at the bottom of the medical report. Legal considerations prevent the processing of claims before these are on file, and of course it is difficult to prepare and send checks without the correct spelling of the doctor's name and address. Therefore, if the persons in the doctor's office who prepare the report would type or print this information in addition to having the physician affix his signature, prompt payment of the claim would follow.

A large measure of Blue Shield's success depends upon co-operation in attending to these items. Such attention will prevent excessive administrative cost and promote subscriber and physician satisfaction through the elimination of delay.

During the year of 1952, Blue Cross paid hospital bills incurred by subscribers in the amount of $12,546,456. Hospitalization expense averaged over a million dollars per month incurred by 167,045 subscribers.

During the year of 1952, Blue Shield paid $3,659,143 incurred by 103,777 participant subscribers.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

OFFICE MANAGEMENT OF OCULAR DISEASES. William F. Hughes, Jr., M.D., Professor and Head, Department of Ophthalmology, University of Illinois College of Medicine, Ophthalmologist in Chief, Illinois Eye and Ear Infirmary, and Attending Ophthalmologist, Presbyterian Hospital, Chicago. 452 pages. Illus. Price $9.00, cloth. Chicago: Year Book Publishers, 1953.

PRACTICE OF PSYCHIATRY. William S. Sadler, M.D., F.A.P.A., Consulting Psychiatrist to Columbus Hospital and Pinel Sanitarium; Fellow of the American Psychiatric Association; member of American Psychopathological Association. 1183 pages. Price $15.00, cloth. St. Louis: C. V. Mosby Co., 1953.

CLINICAL ALLERGY. French K. Hansel, M.D., M.S., Director Hansel Foundation for Education and Research in Allergy; Chief of Allergy Service, DePaul Hospital, St. Louis. 1005 pages. Illus. Price $17.50, cloth. St. Louis: C. V. Mosby Co., 1953.

BACK DOWN THE RIDGE. W. L. White. Author of "They Were Expendable" and many other books. 182 pages. Price $3.00, cloth. New York: Harcourt, Brace & Company, 1953.

CHLOROPHYLL IN MEDICINE. Scientific background, clinical experience in topical therapy, with Chloresium ointment and solution. 52 pages. Illus. Paper cover. Supplied without charge on request. Mt. Vernon, New York: Rystan Company, 1952.

THE STORY OF THE ADAPTATION SYNDROME (Told in the Form of Informal, Illustrated Lectures) By Hans Selye, M.D., Ph.D. (Prague), D.Sc. (McGill), FRS. (Canada), Professor and Director of the Institut de Medecine et de Chirurgie Experimentales Universite de Montreal. 225 pages. Illus. Price, $4.50. Montreal: Acta, Inc., 1952.

As physicians and medical students read and heard about Selye's Adaptation Syndrome, they were interested in knowing about his experiments and what led him to perform them. This book consists of a series of lectures given by Selye in response to this interest.

There are seven lectures in all. The first five lectures contain a chronological account of how the stress concept evolved and how one experiment led to another. The account includes a descriptive characterization of the general adaptation syndrome, the dynamics of it, the diseases of adaptation (i.e., the results of the imperfect functioning of this defense reaction), and the

PATTERSON SURGICAL SUPPLY COMPANY
103 East Fifth St., St. Paul 1, Minn.
HOSPITAL AND PHYSICIANS SUPPLIES AND EQUIPMENT
Cedar 1781-82-83

many variations involved. The sixth lecture is an enumeration both of the principal facts gained from all the research on stress and the adaptation syndrome and of the criticisms directed against the theory. The last lecture is a general summary of the adaptation syndrome concept and a look at some of the questions yet to be answered.

Because this is an informal, personal story, the author has felt free to intersperse his account with bits of his philosophy of research and with admonitions and exhortations to other researchers. It gives glimpses into Selye's enthusiasms, his disappointments, and his triumphs as this concept evolved.

M.M.P.

HISTOPATHOLOGICAL TECHNIC, Including a Discussion of Botanical Microtechnic. By Aram A. Krajian, Sc.D., formerly in Department of Pathology, Los Angeles County General Hospital, Los Angeles, Calif., and R. B. H. Gradwohl, M.D., Pathologist to Christian Hospital; Director, Gradwohl School of Laboratory and X-Ray Technique, St. Louis, Mo. 2d ed. 362 pages. Illus. Price, $6.75. St. Louis: C. V. Mosby Co., 1952.

This is the second edition of Krajian's *Histological Technic*, first published in 1940. Like the first, the current edition presents an excellent exposition of standard staining techniques, as well as Dr. Krajian's own methods of staining reticulum, elastic fibers, amyloid, myelin sheaths, bacteria, treponema pallida, et cetera. Dr. Gradwohl's most notable contribution is a section on Papanicolaou's method for the cytological diagnosis of malignancy. The sections on the dopa reaction and the demonstration of spirochaetes in tissues are also noteworthy.

On the whole, this book is a clearly written, understandable, and up-to-date laboratory manual for the histologist. It is reasonably complete, but there are a few surprising omissions, for a book published in 1952. For instance, there is no mention of the newer methods for staining mucopolysaccharides, such as the various modifications of the leukofuchsin-periodate reaction. The use of toluidine blue is mentioned only in connection with the demonstration of Nissl granules.

This volume is an excellent example of its type—namely, a laboratory manual of histopathologic techniques. It shares the limitations of almost all such manuals, however, in that it is concerned almost exclusively with the *how*, and the *why* is almost completely ignored. In this volume, for example, there is only one short paragraph on the theory of staining, while no less than twenty-six pages are devoted to the use and care of microtome knives. This "cook book" approach makes the book of more interest to laboratory technicians than to physicians.

Robert W. Goltz, M.D.

DERMATOLOGY; ESSENTIALS OF DIAGNOSIS AND TREATMENT. By Marion B. Sulzberger, M.D., Professor and Chairman, Department of Dermatology and Syphilology, New York University Post-Graduate Medical School; Director of Dermatology and Syphilology, Skin and Cancer Unit and University Hospital, New York University-Bellevue Medical Center; and Jack Wolf, M.D., Associate Professor of Clinical Dermatology and Syphilology, New York University Post-Graduate Medical School; Attending Dermatologist and Syphilologist, Skin and Cancer Unit and University Hospital, New York University-Bellevue Medical Center. 592 pages. Illus. Price, $10.00. Chicago: The Year Book Publishers, ©1952.

The authors have completely revised their text "Dermatologic Therapy" and changed the title to "Dermatology: Essentials of Diagnosis and Treatment." The authors state that their book is intended for the medical student, the graduate student in dermatology and the practicing nondermatologist. This book will be of value to the dermatologist, as well. It stresses the diagnosis and management of certain common and selected groups of dermatoses that are seen daily by the general practitioner as well as by the dermatologist.

The book is well organized, well illustrated and outlines practical steps in diagnosis and treatment. It includes the most recent information on the dermatologic uses of antibiotics, ACTH and cortisone. Two chapters are devoted to the diagnosis, course and management of the different stages of syphilis. This is a very worthwhile book for those who are dealing with the management of skin diseases.

Harold G. Ravits, M.D.

DIAGNOSIS OF CONGENITAL CARDIAC DEFECTS IN GENERAL PRACTICE

A new handbook, "Diagnosis of Congenital Cardiac Defects in General Practice," is being distributed by the American Heart Association and its affiliates. This handbook, designed for general practitioners and pediatricians, is intended to clarify the function of the family physician in the diagnosis of congenital cardiac defects and in the management of patients with these defects.

Written by Regina Gluck, M.D., Assistant Clinical Professor of Pediatrics, Children's Medical Service, Bellevue Hospital, New York City, the booklet points out the need for caution in advising on cardiac surgery before a definite diagnosis is made by a specialist. It suggests the advisability of selecting cases for referral to a cardiologist, and outlines the contribution to diagnosis and treatment that can be made by medical-surgical teams in special institutions.

The booklet may be obtained from affiliated heart associations or from the American Heart Association at 44 East 23rd Street, New York 10, N. Y.

a strong start...

Strong muscle development and excellent tissue turgor characterize the *sturdy growth* of babies fed Olac®, Mead's powdered formula.

Olac supplies milk protein in exceptionally generous amounts. Its fat, a single highly refined vegetable oil, is well tolerated and easily assimilated. Dextri-Maltose, supplementing the lactose of the milk, meets energy needs and spares protein. Vitamin A and D supplements are also included in the formula.

Olac is easily mixed with warm water—1 measure to each 2 ounces water makes a formula supplying 20 calories per fluid ounce.

Olac is ideal also for supplementary and complementary feedings of breast-fed babies.

for both full term and premature infants

..Chloromycetin®

is indisputably the drug of choice in typhoid fever and is considered by many to be useful in other salmonelloses

outstanding in acute Shigella dysentery, CHLOROMYCETIN permits immediate treatment regardless of dehydration and provides rapid relief.

exceptionally well tolerated, CHLOROMYCETIN (chloramphenicol, Parke-Davis) is noted for the infrequent occurrence of even mild gastrointestinal side effects, an important consideration in treating infections of the gastrointestinal tract. Although serious blood disorders following its use are rare, it is a potent therapeutic agent, and should not be used indiscriminately or for minor infections — and, as with certain other drugs, adequate blood studies should be made when the patient requires prolonged or intermittent therapy.

Wishful Thinking

Those of you who haven't yet paused in your busy day to provide for adequate income protection, are guilty of wishful thinking. You are hoping that the law of averages will pass you by. Most of us know that you can't depend upon a four-leaf clover.

This Special Disability Policy offers more protection per-dollar than any other contract on the market.

Our counsel is to stop depending upon a four-leaf clover. Call or write this office NOW—Or better yet—stop at our booth, No. 10 at the State Medical Convention in May and visit with us about your accident and sickness program.

Congratulations to the Minnesota State Medical Association on its 100th anniversary!

In celebration of your 100th anniversary, we take this opportunity to extend our heartiest congratulations and sincere best wishes to the hundreds of loyal members that we have had the privilege of serving through the years. All during our 33 years of serving the medical profession, we have endeavored to give our customers the best of service and the highest quality merchandise at most favorable prices. Your continued patronage has shown that you have placed complete faith in our organization, for which we are thankful. To one and all we say a heart-felt "thank you" . . . and pledge for the years ahead to continue and, wherever possible, serve you even better than in the past.

You are cordially invited to visit our exhibit—Booths 92 and 93—at this year's meeting in Saint Paul, May 18, 19 and 20.

NOTES: INTRACTABLE CONSTIPATION

A SUCCESSFUL TREATMENT
WITHOUT HARSH CATHARTICS

Gentle stimulation

When mild bowel stimulation is desired in addition to bulk therapy, Hydrocil Fortified is both safe and effective. Hydrocil Fortified absorbs liquids with unusual efficiency, creating 35 times its own weight of moist, lubricating bulk. It also supplies 3 mgm/5 gm acetphenolisatin, a newly-developed synthesis of the laxative principle in prunes.

Safe, effective

Acetphenolisatin is mild[1], yet on a weight for weight basis is considerably more effective than other common laxative drugs[2]. It is not absorbed, and is apparently non-irritating to the intestinal mucosa. As far as known, no tolerance is developed[3].

Indications

Hydrocil Fortified has proved highly successful in correcting intractable constipation. When prescribed after anorectal surgery, its bulk-producing agents afford natural dilation of the anal canal during passage of the stool. Its fortifying ingredient tends to prevent postoperative impactions.

How supplied

Hydrocil Fortified (blue label) and Hydrocil Regular (brown label) are provided in 4-oz. and 1-lb. canisters. A supply for trial will be sent on written request to Dept. M2, Fuller Pharmaceutical Co., 715 So. 10th St., Minneapolis 4, Minn.

. . . "truly extraordinary" results in intractable bronchial asthma

Cortone®

ACETATE

(CORTISONE ACETATE, MERCK)

In a review article on hormonal therapy,[1] complete relief of symptoms was reported in 62 per cent of 116 asthma patients. Another 24 per cent were made "quite comfortable." Duration of relief varied widely, with remissions occasionally lasting as long as several months. The author calls these results "truly extraordinary."

"Anxiety is the great modern plague"

By providing mild synergistic sedation at three important sensory and reflex levels of the nervous system (brain, spinal cord, and neuromuscular junction of smooth muscle) instead of focusing relatively intensive pharmacological action at but one of these levels;

Completely balanced psychosomatic sedation for the treatment of Visceroneurosis is obtained

"Just remember that it's not what they eat that's causing their ulcers; it's what's eating them."

Synergism in clinical medicine is sufficiently rare to warrant special attention whenever demonstrated or even indicated.

over 100,000

diabetes detection centers!

"The ideal detection center is

the office of the family physician."[1]

Increasing experience in diabetes case-finding indicates that intermittent surveys and mass screening drives, although useful, have certain limitations. Getting and others,[2] in evaluating a community detection campaign (well publicized in the area), report that only 59% of persons accepting the free testing materials actually performed the test. Only 24% of those with positive results sought medical advice.

To find the estimated one million unknown diabetics[3] and place them under needed medical care, the indispensable factor for success is the activity of the individual physician.

Cordelia

AWARD WINNING BRASSIERES!

Cordelia surgical brassieres have won the Blue Ribbon for five consecutive years. Now, Cordelia has won BOTH the GOLD MEDAL and BLUE RIBBON AWARDS at the 1952 California State Fair Fashion Exhibit.

When she asks...

HERE ARE THE FACTS!

Most corrective, surgical and maternity brassiere problems have been scientifically solved by the staff of Physiospecialists at Cordelia of Hollywood.

THE GOLD MEDAL WINNER!

Each Cordelia brassiere is planned and made for easy, individual fittings by experts in local stores.

THE BLUE RIBBON WINNER!

Every Cordelia brassiere is a luxury in fashion fabrics — beautifully, youthfully designed. These are the facts judges took into consideration — then awarded *Cordelia the winner!*

PICKER-POLAROID "ONE MINUTE X-RAY" is now available for CIVILIAN use

You've probably already heard of the "one-minute" Picker-Polaroid radiograph. Introduced a little over a year ago, this dramatic development was immediately accepted by the Armed Services which requisitioned the entire output for military needs. Ever since, we have been struggling to increase production to the point where parallel civilian needs could at least be partly met. That point has now been reached. Limited quantities are becoming available to civilian users.

The Picker-Polaroid system is an adaptation to radiography of the self-development principle of the Polaroid Land Camera. The whole job takes only a minute . . . can be done in broad daylight . . . needs no darkroom, no solutions, no dryer. It is all incredibly simple and quick: (a) you load the cassette (b) make the exposure (c) put the cassette in the automatic processing box. Wait sixty seconds: open the box and there's your finished radiograph . . . flat, dry, ready for use. Its speed and convenience have already proven invaluable in the operating room for hip-pinning and similar procedures; for emergency hospital admissions, for work with portable and mobile x-ray units.

Since quantities are still limited, those wishing to obtain Picker-Polaroid equipment supplies would do well to communicate at once with either their local Picker office, or with Picker X-Ray Corporation, 25 South Broadway, White Plains, New York.

Confidence...

IN ESTROGENIC THERAPY

To restore hormone balance in treatment of the menopausal syndrome, functional primary amenorrhea, ovarian hypogonadism, senile vaginitis, pruritus vulvae . . .

ALPHA-ESTRADIOL, U. S. P. Chimedic
For Intramuscular Administration

The primary follicular hormone as secreted by the ovary—provides rapid control of symptoms, yet is absorbed slowly and uniformly assuring prolonged estrogenic activity and efficient utilization of the hormone.

According to the U. S. Dispensatory, among the natural estrogens ". . . only estradiol, estrone and estriol have sufficient activity to warrant their use individually. When given by injection, estradiol is the most active of the three substances . . ."[1]

1. U. S. Dispensatory, 24th ed., p. 432

DIETHYLSTILBESTROL, U. S. P. Chimedic
For Oral Administration

A pure synthetic estrogen—is the most potent of the stilbene compounds. "Diethylstilbestrol possesses the advantage of being highly active by mouth . . ."[2] "Its physiologic activity duplicates practically all the known actions of natural estrogens."[2]

Diethylstilbestrol Chimedic provides a convenient oral form of estrogenic therapy with uniform level of estrogenic activity.

2. New and Nonofficial Remedies, 1952, p. 342

For the treatment of estrogenic hormone deficiency states, CHIMEDIC hormone preparations satisfy the most exacting requirements for purity, potency and effectiveness.

Dear Doctor:

Usually Inadequate

℞
Tolserol Tabs. 0.5 gram
Disp. #100
Sig: One tablet 3 to 5 times a day. Take after meals or with 1/3 glass of milk.

This prescription is typical of many written for Tolserol Tablets*, as seen in a recent prescription survey.

Although some patients will respond to such low dosage, much better results can be obtained by following the recommended dosage: 1 to 3 grams, 3 to 5 times per day.

In accordance with this recommendation, the first dosage schedule for a patient could be:

Better

℞
Tolserol Tabs. 0.5 gram
Disp. #100
Sig: Two tablets 3 to 5 times a day. Take after meals or with 1/3 glass of milk.

Complete information on the use of Tolserol in muscle spasm of rheumatic disorders, neurologic disorders, and acute alcoholism is available from your Squibb Professional Service Representative.

Sincerely yours,
L. H. Ashe

. . . all the patients who represent the 44 uses for short-acting

NEMBUTAL®

Ever wonder why one drug should survive 23 years of clinical experience (when a lifetime for many is only about five)? Why it should account for 598 published reports? Or more than 44 clinical uses?

Short-acting Nembutal (Pentobarbital, Abbott) is the drug. The reasons why?

1. Short-acting Nembutal can produce any desired degree of cerebral depression—from mild sedation to deep hypnosis.
2. The dosage required is small—only about half that of many other barbiturates.
3. There's less drug to be inactivated, shorter duration of effect, wide margin of safety and usually no morning-after hangover.
4. In equal oral doses, no other barbiturate combines quicker, briefer, more profound effect.

How many of short-acting Nembutal's 44 uses have *you* tried? You'll find details on all in the booklet, "44 Clinical Uses for Nembutal." Write Abbott Laboratories, North Chicago, Illinois. Abbott

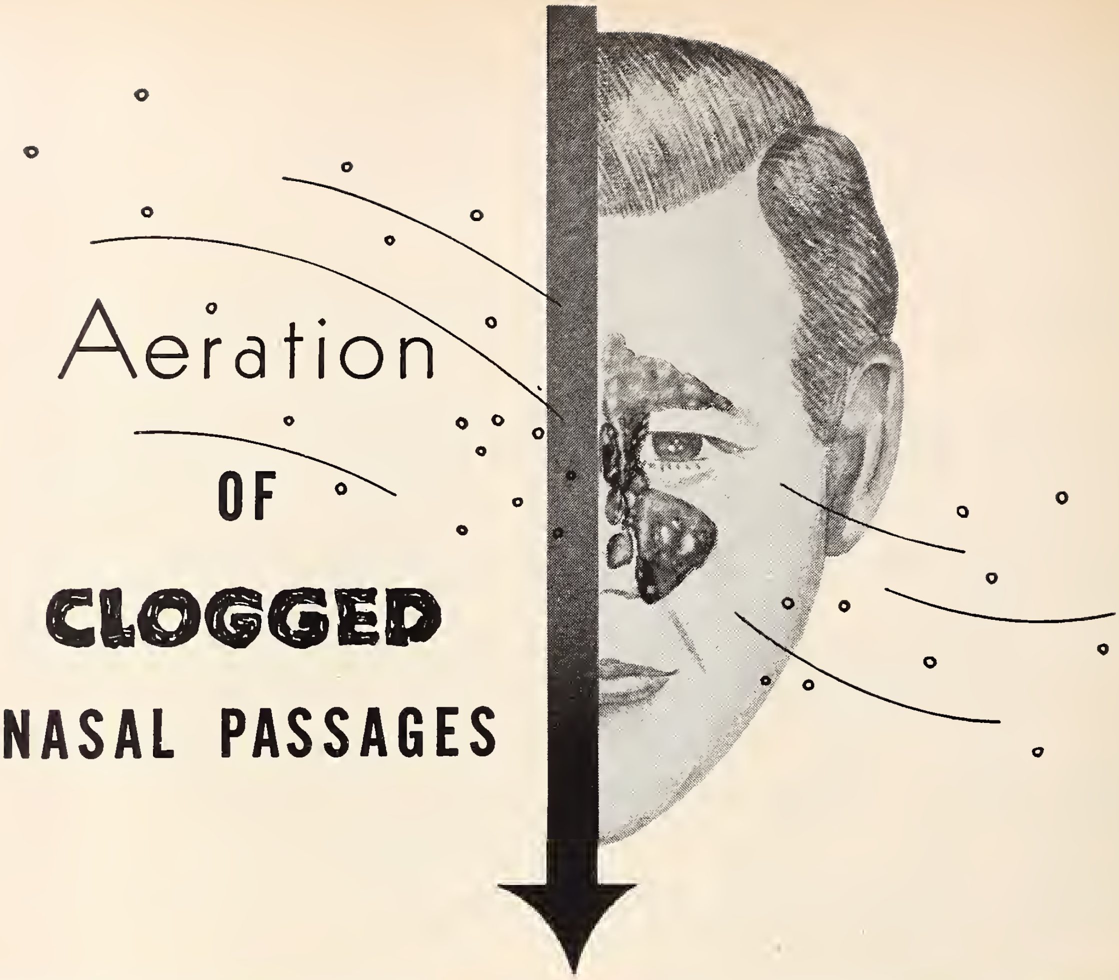
Aeration OF CLOGGED NASAL PASSAGES



Breathing comfort as well as proper drainage and aeration of the sinuses during upper respiratory infections is assured by the swift and prolonged decongestive action of

NEO-SYNEPHRINE®

HYDROCHLORIDE

By shrinking the swollen mucosa, Neo-Synephrine permits drainage of purulent matter, restoring free breathing and relieving the headache caused by clogged passages.

RAPID AND PROLONGED ACTION Clearing of nasal obstruction follows within seconds after application of Neo-Synephrine and is unusually prolonged, so that comparatively few daily applications are necessary throughout the course of a cold.

WELL TOLERATED Neo-Synephrine is notable for its relative freedom from sting, virtual absence of compensatory congestion and also has been found relatively free from systemic side effects such as nervous excitation, cardiac reaction or insomnia even when tested on hypertensive, cardiac and hyperthyroid patients.[1]

NO APPRECIABLE INTERFERENCE WITH CILIARY ACTIVITY Neo-Synephrine not only restores nasal patency, but is compatible with ciliary action.

NO DROWSINESS Neo-Synephrine may be used by the ambulatory patient without danger of producing drowsiness or related sedative action. Applied topically, Neo-Synephrine confines its action to the upper respiratory passages.

SUPPLIED:

0.25% solution (plain), 1 oz., 4 oz. and 16 oz. bottles.

0.25% solution (aromatic), 1 oz. and 16 oz. bottles.

0.5% solution, 1 oz. bottles.

1% solution, 1 oz., 4 oz. and 16 oz. bottles.

0.5% water soluble jelly, 5/8 oz. tubes.

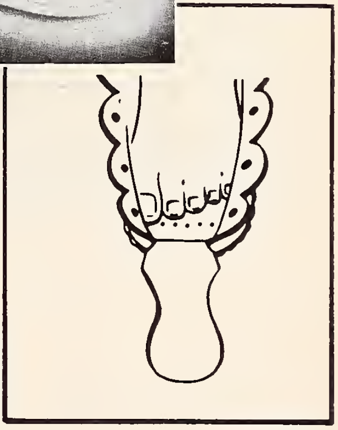
A NEW APPROACH TO THE DIFFICULT PROBLEM OF CORRECTLY FITTING *and* PROTECTING PRE-WALKING FEET

tattle-toes are the first improvement in Pre-walking and First-Step Shoes in this Generation.

tattle-toe Shoes are Soft

Tiny feet are tender. Hard, stiff shoes can be most detrimental to soft baby feet. The first quality of babies shoes should be softness. Softness, not only of material, but even more important is the softness of construction. A soft construction is one that produces a shoe that can easily be folded in your hand and then easily returned to its original shape.



VISUAL FITTING

The growth line exclusive in Tattle-Toes provides Mother with a positive gauge to measure the position of baby's feet.

"Today's Health", published by the American Medical Association, has awarded its emblem of acceptance to Tattle-Toes for advertising in "Today's Health".

ONE HUNDRED YEARS OF ORGANIZED MEDICINE IN MINNESOTA

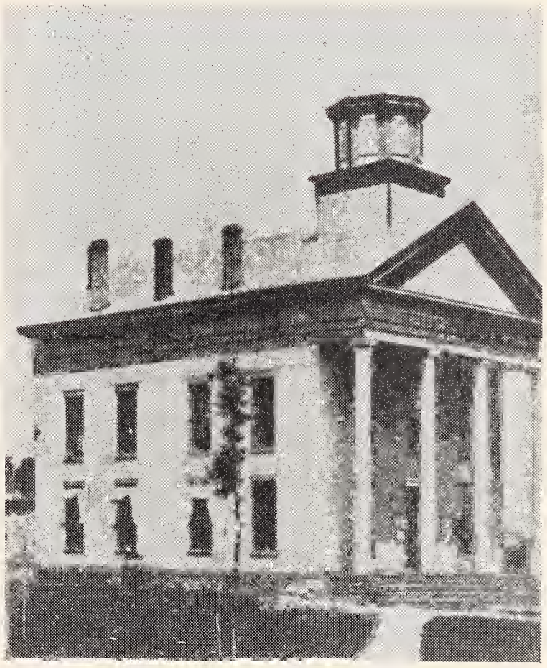
History of the Minnesota State Medical Association, 1853-1953

ROBERT ROSENTHAL, M.D.
Saint Paul, Minnesota

ONE DAY in July, 1853, eleven enterprising young doctors gathered in the fine new Court House of Saint Paul in the Minnesota Territory for the purpose of organizing a medical society. They were men of considerable education, these doctors. Many of them had studied for as much as two years in the university medical schools of Massachusetts, Pennsylvania, New York, Ohio, and at Rush Medical school in Chicago. Quite a few of them had come to the Northwest country for their health.

Ten years before, there had been just one civilian doctor west of Prairie du Chien. His name was Christopher Carli. He had started his long travels into the new world from Heidelberg and finally settled in Stillwater. Now there were fifteen or sixteen, most of them newly arrived from the East. In fact, nothing in previous history matched the speed with which easterners were now pouring into the territory and building up the new town of Saint Paul. Churches and schools appeared like magic; also a bank, a hotel, newspapers and even an insurance company. With equal speed, the doctors, some of whom had hardly had time to hang out their shingles, now set about organizing a medical society.

The political climate was favorable but turbulent times were just ahead. Alexander Ramsey was the territorial governor and Henry Sibley of the American Fur Company represented the territory in Congress. The settlers were mainly traders, lumber men and real estate speculators. All of them were clamoring for an end to the negotiations with the Indians, and the opening of the rich lands in the river valleys to the West and South. The Civil War was less than ten years away and the great land boom which was to collapse in 1857 was in the making.



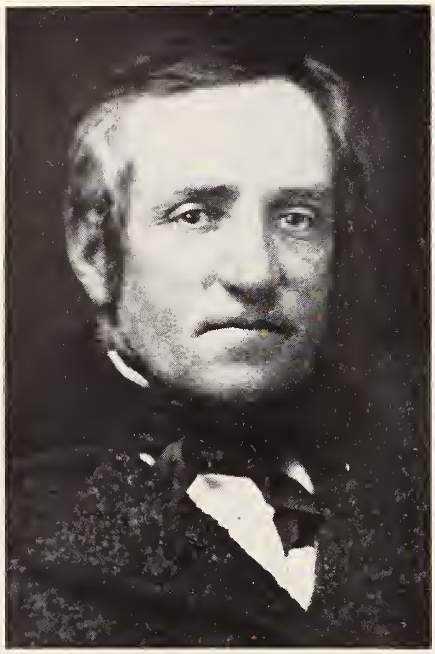
THE COURT HOUSE IN SAINT PAUL
MINNESOTA TERRITORY

Building in which the Minnesota State Medical Association was organized in July, 1853.

The shrill creaking of ox carts still sounded twice a year as the traders journeyed down to the river from the Red River trail of the North. But the doctors who rode to the Court House on that July day were neither traders nor frontiersmen. They were physicians when they arrived at this upper Mississippi outpost and they were destined to play a considerable role as citizens, as well as doctors, in the development of Minnesota.

Dr. Rosenthal is chairman of the Historical Committee of the Minnesota State Medical Association.

A few medical societies in the United States date back to Revolutionary times. The Medical Society of New Jersey was organized in 1766, the Massachusetts society in 1781 and the Medical Society of Delaware in 1789. Perhaps a dozen more societies came into existence in the first half of the nineteenth century including the State Medical Society of Wisconsin in 1841 and the Iowa State Medical Society in 1847.



Dr. Thomas Reid Potts

First President of the Minnesota State Medical Association (then known as the Minnesota State Medical Society).

The settlements and the trails, the river fronts and the trading posts of the new Minnesota territory already abounded in quacks and Indian healers of all descriptions when the call for the first meeting of regular practitioners in Minnesota was published in *The Minnesotian* of July 16, 1853.

"We are requested to state" said this announcement, "that the medical profession of the territory will hold a convention at St. Paul on the 23rd instant."

The meeting was held as announced and the proceedings were published in the *St. Anthony Falls Express* of July 30, in *The Minnesotian* and *The Democrat* of that month, and in the *Northwestern Medical and Surgical Journal* of Chicago in the August issue of that year. A constitution and by-laws, modelled on those of the Pennsylvania and Illinois societies, were adopted. Committees on Arrangements, on the Practice of Medicine, on Surgery, Obstetrics, Drugs and Medicines and on Publication were appointed. Resolutions were passed applauding the stand taken by the National Medical Association on intoxicating drugs and medicines and pledging the new society to cooperate with the national body. Officers were elected and a meeting place selected for the 1854 meeting. All of these will certainly strike the medical ear of one hundred years later as standard procedure for the conduct of medical meetings.

The men who were elected to office that day were already important men in the community. They were headed by Dr. Thomas Reid Potts as president. Dr. Potts was elected President of the Board of Trustees of the town and may well be called the first mayor of Saint Paul. He had been educated at the University of Pennsylvania Medical school. He was a relative of Henry Sibley and a leader in the territory. He came to Saint Paul in 1849 and was perhaps elected because he was much the oldest man present. He was forty-four years old at the time.

The vice presidents were Dr. John H. Murphy of St. Anthony Falls and Dr. A. E. Ames who had established himself across the river from St. Anthony in the settlement which later became Minneapolis. Both were from Rush Medical College in Chicago, but Dr. Murphy had arrived in 1849 and Dr. Ames had been in the territory since 1851. The names of both were to loom large in subsequent history of the society and of Saint Paul and Minneapolis. The corresponding secretary was Dr. T. T. Mann who had come west for his health in 1852 after graduation from the University of Pennsylvania and an extended tour of Europe. Dr. Charles L. Anderson of St. Anthony Falls was recording secretary. Dr. Anderson had come to the territory the year before and was a distinguished naturalist as well as physician. Henry Thoreau was to visit him later in St. Anthony Falls and Minneapolis. The treasurer was Dr. James D. Goodrich of Saint Paul who, like so many others, had come to Saint Paul for his health the year before. He had practiced for several years in Cleveland and was to become Saint Paul's first health officer later on.

The censors were Drs. J. H. Day, W. W. Finch and John J. Dewey. One of these three, Dr. Finch, had come to Saint Paul from Vermont that very year but moved later to Steele County. The other two, Dr. Day and Dr. Dewey, were leading figures in the early history of the territory. Dr. Day was practicing with Dr. Carli in Stillwater at the time. He had arrived in 1847 and had served as the first Register of Deeds and recorded the first deed in Ramsey county. He was also an architect, apparently, since he is said to have drawn the plans for the new court house, built just the year before the meeting. It was an imposing square frame building with a colonaded entrance, and his fee for the plans was reported to be $10. Dr. Dewey, the other censor, came to Saint Paul in 1847. He was educated at the Albany Medical College and he established the first drug store in Saint Paul in 1848. He also had the distinction of being the first physician to settle permanently in Saint Paul.

Members of the Committee on Arrangements were Drs. Murphy and Anderson and Dr. A. E. Johnson who had just arrived in 1853 and had settled in Hennepin with Dr. Anderson. Dr. Johnson came from New York. He was graduated from the Columbia Medical school and he was also a naturalist and ethnologist of note. Later he founded the Minneapolis Academy of Natural Sciences.

The Committee on the Practice of Medicine was composed of Drs. Carli and Anderson and Dr. A. G. Brisbine who had come to Saint Paul from Ohio in 1851, a graduate of Jefferson Medical College.

Dr. Charles McDougall was the military surgeon from Fort Snelling. He had arrived very recently to take the place of Dr. Ames who had served briefly there as contract surgeon, and he was appointed to the Committee on Surgery, together with Drs. Ames and Day. Drs. Potts, Murphy and Mann were named to the Committee on Obstetrics. The Committee on Drugs and Medicines was made up of Drs. Goodrich and Mann and Dr. Samuel Willey, all of Saint Paul. Dr. Willey had come to Saint Paul because of tuberculosis in 1852. He had graduated from Yale and from the Cleveland Medical College and, although he was reported to have arrived with exactly fifty cents in his pocket, he was soon well established in practice with Dr. Brisbine. Promptly he became a dashing figure in Saint Paul society. He was president of the association at the re-organization in 1869, and in 1870 he served as vice president of the American Medical Association.

All of these men were present in person at the meeting except Drs. Carli, Day, Willey, Brisbine and McDougall who were accepted as founding members at their own request.

Dr. A. W. Daniels was there that day, too, by special summons. So was Dr. O. P. Marsh of Saint Paul, according to the account in the *St. Anthony Falls Express*. Dr. Marsh apparently had arrived in Saint Paul only a very short time before, but Dr. Daniels was the only man present from outside Saint Paul, St. Anthony Falls, Hennepin and Stillwater. Dr. Daniels had come from New Hampshire but had graduated from the Medical College of Ohio at Cincinnati in 1853 and had been appointed, at about the same time, assistant surgeon at Fort Ridgley in the western part of Nicollet County. Later he became resident physician to the Lower Sioux in Redwood County. Later still, he moved to St. Peter where he practiced for many years.

The new society chose Dr. Murphy as its delegate to the so-called National Medical Association, and the transactions of the American Medical Association at St. Louis in 1854 duly recorded his presence as delegate from Minnesota. Actually, he was not the first doctor from the upper Mississippi to attend a national medical meeting. Dr. Ames had been at the meeting of 1848; and so had Dr. Daniels, Dr. Marsh and Dr. Johnson. The habit of attending meetings was obviously well established among medical men before the organization of the Minnesota medical society.

It was agreed at that first meeting that the society would meet again in June, 1854; but if the 1854 meeting was held, no record of it remains. The society was evidently regarded as a going concern in 1856, however, because the *Minnesota Republican* of January 17 recorded an election of officers under the caption, "Minnesota Medical Society." Dr. Potts of Saint Paul was still the president; Dr. Murphy of St. Anthony Falls was the vice president. The corresponding secretary was Dr. Goodrich of Saint Paul and the recording secretary was Dr. J. V. Wren of Saint Paul, who had apparently been in the territory for a few years but was more preacher than doctor; he was also said to be more interested in politics than medicine. The treasurer was listed as Dr. Day who had now moved to Saint Paul, and the censors were Dr. Ames of Minneapolis, Dr. Johnson of St. Anthony Falls and Dr. Franklin R. Smith of Saint Paul. Dr. Smith had practiced for a number of years in Pennsylvania before he settled in Saint Paul in 1855. He was a Quaker and greatly respected by fellow practitioners, particularly as an obstetrician. The Committee on Publication was composed of Drs. Ewing (also called R. W. Wing in the Saint Paul City Directory of 1856-57), Marsh of Saint Paul and C. L. Anderson of Minneapolis. The meeting at which these officers were elected was held, according to another account, on January 3, 1856, in Dr. Wren's office.

In the Saint Paul City Directory of 1856-57 virtually the same names appear as officers of the Minnesota Medical Society, though the names of two newcomers, Drs. W. H. Morton and J. H. Stewart, of Saint Paul, are added to the censors and the names of Drs. R. W. Wing and O. P. Marsh of Saint Paul, and Charles L. Anderson of Minneapolis appear as members of a standing committee.

This is the last mention of the society in print at the time, though in the proceedings of the meeting of 1869, at which the society was reorganized, there is the following statement:

> "Two subsequent meetings were held, (after 1855) the last being at St. Anthony in 1857. After that period the society was allowed to languish. The Rebellion broke out and a large number of members entered the service and no meetings have been held, until the call appeared under which the society assembled today at 11:00 a.m. at the International Hotel."

The outbreak of war undoubtedly delayed the re-organization of the society. Most authorities believe it was the panic of 1857 which killed off society activities after that year, however, just as it killed so many business activities of the time. All of the doctors who did not go elsewhere were too busy, for a while, trying to survive the hard times to have any attention left over for medical organization.

When they did meet again it was with Dr. Potts and the officers of the old society in charge. But the picture in medicine, as in the state and the country, had changed almost past recognition. It was 1869 and the Civil War was over. The frontiers had been pushed back far beyond the Mississippi. Minnesota was a state, now, and there were doctors represented, even at this initial meeting, from Red Wing, Rochester, St. Peter, Austin, Albert Lea, Owatonna, Carver, Luverne and Mankato as well as Minneapolis, Saint Paul and Stillwater. Among these new, outstate representatives was Dr. W. W. Mayo who had paused briefly in Saint Paul in 1854, but had pushed on to Le Sueur and then to Rochester.

The notice of the meeting which was printed in Saint Paul papers of January 20 and 21 announced that "business of importance" would be presented. This business of importance was undoubtedly the presentation of a possible medical practice act to be passed by the Legislature, then in session. In due course, a resolution was passed at the meeting to the effect that, "in case the Legislature now assembled desire to protect the citizens of this state against quackery, it is the duty of this society to cooperate with the Legislature and lend its assistance in framing all needful laws upon the subject; and that Drs. Willey, Sheardown, and Stewart be appointed a committee as the organ of the Society for this purpose." But this was not the only business of the 1869 meeting.

The meeting convened with Dr. Potts shortly assuming the chair and Dr. D. W. Hand acting as secretary. Dr. Ames was there representing the 1857 committee of censors and he proposed a list of thirty-nine names for acceptance by the credentials committee made up of Drs. J. H. Stewart of Saint Paul, N. B. Hill of Minneapolis and Dr. Mayo. These thirty-nine men, together with the officers, were seated in the convention. They included Drs. E. J. Davis and J. C. Jones of Mankato; W. W. Mayo and E. W. Cross of Rochester; S. B. Sheardown of Winona; J. A. Allen of Austin; A. W. Daniels of St. Peter; O. Ayer of Le Sueur; N. B. Hill, C. G. Goodrich, Charles A. McCollum, W. F. Hutchinson, J. J. (H. H.?) Kimball, J. H. Churchill, C. J. Dubois, H. A. Dubois, O. J Evans and A. H. Lindley, all of Minneapolis; Samuel Willey, J. H. Stewart, Alfred Wharton, D. W. Hand, S. D. Flagg, Brewer Mattocks, Charles E. Smith, E. H. Smith, A. G. Brisbine, John Steele, M. Hagen, J. B. Phillips, Adelard Guernon, all of Saint Paul; W. A. Griffin and C. E. Rogers of Carver; W. W. Sweney and Charles Hewitt of Red Wing; A. C. Wedge, Albert Lea; J. C. Rhodes and H. F. Noyes of Stillwater and Solomon Blood of Owatonna.

There were differences of opinion as to the procedure to be followed but eventually the convention decided to adopt the old constitution and by-laws and a new set of officers was elected forthwith. They were Drs. Samuel Willey, Saint Paul, president; A. E. Ames of Minneapolis, vice president; Alfred Wharton of Saint Paul and E. J. Davis of Mankato as corresponding and recording secretaries, respectively. The treasurer was Dr. S. B. Sheardown of Winona and the censors were J. H. Murphy who had moved from St. Anthony Falls to Saint Paul, N. B. Hill of Minneapolis, W. W. Mayo of Rochester, A. C. Wedge of Albert Lea, and J. C. Rhodes of Stillwater. There was also a Standing Committee made up of Drs. A. G. Brisbine of Saint Paul, E. C. (or C. E.) Rogers of Carver and J. E. Finch of Hastings. All this was accomplished at the morning session.

In the afternoon, they decided to revise the constitution and by-laws and appointed a committee to do it. They appointed a committee on finances, too, and decided on an assessment of $2.00 a year per member which would certainly be ample to meet current expenses. They decided to have two meetings a year in different localities of the state, a practice which continued for a number of years, and chose Owatonna for the June meeting that year. Three men were selected on the spot to deliver addresses at the meeting. They were Drs. Ames, Hewitt and Kimball and the program, selected by a committee composed of Drs. Hewitt, Noyes and Sheardown, was to be as follows:

"1. Essay on Rheumatism—Dr. Kimball
2. Discussion of Dr. Kimball's essay. Led by Dr. Wharton of Saint Paul and A. B. Stuart of Winona.
3. Discussion of Quackery, Its Diagnosis and Treatment. Drs. Brewer Mattocks and Hewitt of Red Wing were to lead the discussion.
4. Adjournment to 7 p.m. to hear the address by Vice President Ames of Minneapolis.
5. Reports of Committees and Adjournment."

The members also accepted the suggestion of Dr. Blood of Owatonna that every member be requested to report a case from his own practice at each meeting. At his suggestion, also, a committee was appointed, composed of one member from each county, to report on the number of physicians practicing in their respective counties including both regulars and irregulars.

This last committee reported at the Owatonna meeting which convened as planned on June 16, 1869, at Dresser's Hall. The committee had found physicians in practice in Ramsey, Hennepin, Washington, Dakota, Fillmore, Houston, Wabasha, Steele, Olmsted, Goodhue, Winona and Dodge counties. The largest number were in Ramsey and Hennepin counties, though Fillmore and Winona counties were close seconds. The total number of regular practitioners was 119 and the total number of irregulars not recognized by the societies was ninety-three.

The concern of the society of 1869 about irregulars and quacks was therefore not to be wondered at. The legislation developed from the action taken at the re-organization meeting had actually passed the Legislature on March 4, 1869, and high hopes were no doubt entertained for it. The truth is, however, that results were disappointing. In the first place, there was no adequate means of determining whether or not a diploma had been forged or stolen. Furthermore, the country was overrun with obscure, inadequate diploma mills. Also, there was the State Homeopathic Institute, founded in 1867, which was given the same right of conferring degrees as any medical school. But the homeopaths, instead of restricting their diplomas, bestowed them upon any passing quack who expressed a belief in homeopathy. The result was that the doctors who had worked to secure passage of the act of 1869 now worked just as hard to secure its repeal; and Minnesota had no further medical practice act on its books until 1883.

At the Owatonna meeting, Dr. J. C. Rhodes of Stillwater introduced a motion prohibiting admission of any person to membership in the society who could not produce satisfactory evidence of being a legal practitioner of medicine. The resolution was adopted, but the amount of discussion showed how difficult the whole matter of applying standards was, even among so-called legal practitioners. In fact, Dr. Mattocks' scheduled discussion of "Quackery" precipitated such a lively debate on what was and what was not quackery that the whole matter appears to have been dropped in favor of less controversial subjects such as typhoid fever.

It is interesting to note that the president, Dr. Willey, offered two prizes out of his own pocket for competition among the members. One, for $50, was for the best essay on "Epidemic and Endemic Diseases of Minnesota." The other, also for $50, was for the best essay on "Cerebro-spinal Meningitis." These prizes figured thereafter for some years in the proceedings of the society. There was seldom any competition for them and only one essay was submitted, usually, for each prize. The first winner, Dr. W. W. Sweney of Red Wing, won both prizes and endorsed his winnings over to the society to establish a "prize fund."

The February meeting of 1870 was notable for the adoption of an amended constitution and by-laws which set up an elaborate mechanism for examining prospective members for the diploma of membership in the Society. Thirty new members from many parts of the state were accepted for membership and the first presidential address, provided for in the amended constitution, was given by Dr. Willey. It was a genuinely distinguished address with overtones that were to be heard, year by year, to this day in the addresses of his successors.

Dr. Willey called for the keeping of vital statistics by the members themselves, since there was no other agency to do it. He called for specialism, but with a sound basis of experience in all fields of practice. Also, he called for laws to curb quackery and for strict adherence to the code of ethics of the American Medical Association in the relationships of members to each other and, especially, to younger men just entering practice. It is worth noting that the special committee appointed to report on the president's address, while heartily approving most of his suggestions, sadly remarked that laws regulating the practice of medicine "do not and cannot reach the cause of the success of quackery among the people, but that the cause is to be found in the deficient knowledge on the part of the people in regard to the real ground upon which the practice of medicine rests, and that, so long as that deficiency exists, quackery will flourish. If legislative action is to be had, it should be directed to the removal of that cause." Dr. Charles N. Hewitt of Red Wing who was soon to become the head of the first state health department, signed the report as chairman. Both Dr. Willey and Dr. Hewitt were paving the way, however, for establishment of two fundamental functions of their association in the next half century, to foster protective legislation and also to foster public education as a means of destroying quackery.

To follow the year-by-year history of the Association from 1870 is obviously impossible in a brief review. The extended history of the Association by Dr. Arthur S. Hamilton was published serially in MINNESOTA MEDICINE beginning in January, 1942. That account and Dr. Hamilton's History of the Hennepin County Medical Society and the History of the Ramsey County Medical Society by Dr. J. M. Armstrong, as well as histories of other county societies of the state, published from time to time over a period of several years in the same journal, should be read for their delightful detail about the life and times of the men who founded and carried on the Association, as well as for the continued story of its development.

From the year 1870, meetings were held regularly at the scheduled times, with more and more men from all over the state participating in the program. Scientific papers began to take on a far more varied and extensive character each year. Their subject matter accurately reflected the tremendous development of scientific medicine in Minnesota and the world outside.

In the early years, Minnesota doctors were greatly preoccupied with consumption and the effect upon it of Minnesota's climate. Many of the early physicians suffered from tuberculosis and came to Minnesota in the hope of being cured. Newspapers refused to admit that lung disease could exist in the territory and some of them, like the *St. Anthony Falls Express,* exhibited actual hostility to the coming of doctors to the territory. They were regarded as useless except, perhaps, to aid the midwives and to bandage the wounds of Indians. The doctors, themselves, soon recognized the fact that Minnesota air, alone, was not accomplishing the expected miracles. For a while they temporized with the assumption that the scent of pines had a therapeutic effect and that, when the pines were cut down, the effect was dissipated. In 1872, however, Dr. Hewitt reported to the American Medical Association meeting of that year that persons with developed phthisis could not expect relief from Minnesota's climate.

Cholera appeared in the territory in 1849 and became epidemic in 1854. Typhoid fever was a constant problem. So were smallpox, diphtheria and rheumatism. Surgeons practiced without the aid of anesthetics, though many of them were undoubtedly aware of the properties of ether, since Long's first use of it in a surgical operation had taken place in 1842 and Morton's famous operation had occurred in 1846. In 1854 Dr. W. W.

Finch of Saint Paul made this announcement in the newspaper: "Being familiar with the Use of Ether, operations in surgery will be performed under its influence without pain, if desired."

Many other great milestones of medicine were established in the years between 1853 and the turn of the century and news of them reached the frontiers of America with remarkable speed, considering the difficulties of communication. Preventive medicine received a great boost with the establishment, through the efforts of the Minnesota State Medical Society, of a state board of health, the third such board in the entire country. Only Massachusetts in 1867 and California in 1870 had preceded it. The act was drawn up at the society's meeting of 1872 in Saint Paul. The society also proposed a bill legalizing dissection at that meeting. Both were passed by the Legislature, though not without a fight. Dr. Hewitt was made secretary and continued in the post until 1897 with a salary, the first year, of $200, a figure which was no measure of the energy, devotion and progressiveness which he brought to the office. Largely due to his pioneering efforts, and the efforts of the individual members, vaccination got an early start in Minnesota. Within a relatively few years, smallpox ceased to be a major preoccupation of the members at their meetings. Diphtheria continued to be a source of worry. At the seventeenth meeting in 1885, Dr. A. E. Spalding of Luverne reported on the use of antitoxin in seven cases, "too few for sufficient proof," he said, "but . . . I cannot help but feel that we have reason to take courage." A committee reported on the use of it in 643 cases the next year, with a drop from a 16.17 death rate to 12.09; but acknowledged that many of the patients were treated too late and with too small a dosage. Few who were present that year had had any clinical experience with the marvelous new treatment, but by 1898, the same committee was able to report "that no remedy ever came to trial that stood the test and became standard so soon."

Antiseptic surgery or "Listerism," as it was called, had considerable prejudice and opposition to overcome in Minnesota, as elsewhere. Lister had begun his great work in antiseptic surgery about 1870; but at the twelfth annual meeting of the Minnesota State Medical Society in 1880, Dr. A. C. Wedge of Albert Lea devoted his entire presidential address to Listerism and regretted that he had been "unable to learn of a single case in which the Lister method had been followed in Minnesota." At the same time, he did think that a large number of men were using disinfectants to some extent.

Dr. Perry H. Millard of Stillwater was president at the fifteenth annual meeting of the Association in 1883 and he devoted his entire presidential address to the work of Pasteur and Lister and the new bacteriological science. "We hope denunciations of Lister have now reached their height," said Dr. Millard, "and we prophesy fame next to none for Dr. Lister."

The year 1883, and the presidency of Dr. Millard, marked another milestone in the history of the Association and of medical practice in Minnesota. In that year, with the backing of W. W. Folwell, president of the new University of Minnesota, Dr. Millard and Dr. Hewitt organized a special examining board for physicians in connection with the University, and secured passage of another medical act. No actual medical teaching had yet been inaugurated at the University. Candidates for examination came from private schools. Each year, Dr. Millard reported to the society, at its annual meeting, on the progress of the new board. Two hundred unqualified physicians had left the state rather than face examination, he reported in 1884. In 1883, there had been 1,183 physicians in the state of whom at least one-third were irregulars. In 1886, he reported only 995 physicians remained. Of eighty-six examined that year by the board, only one had been licensed to practice. The tremendous task of standardizing medical schools and cleaning out the diploma mills was going on under the guidance of the American Medical Association and, apparently, graduates of only seventeen schools were being recognized by the Minnesota board.

In 1887, Dr. Millard, with the aid of the society, persuaded the Legislature to create an independent Board of Medical Examiners in which was vested the exclusive right to admit to practice in Minnesota. It was the first act of its kind to be adopted anywhere in the United States and it signalized the later advancement in medical licensure in Minnesota. Having cleared the way for proper licensure of its students, the University was now ready to establish its medical school and Dr. Millard set out to persuade the private schools, the Minnesota Hospital College of Minneapolis, the Saint Paul Medical College and the Minnesota College of Homeopathic Medicine, to merge into a single department of medicine at the University.

It was thus that Dr. C. F. McComb of Duluth was able to hail the inauguration of medical teaching at the University in his presidential address of 1888. He threw the weight and influence of the organization behind the new school and Dr. Millard.

The seven league strides made in surgery during those years were facilitated, of course, by anesthesia and Listerian methods of antisepsis and by the growth of hospitals. They were also facilitated by the emergence of a series of great surgeons in all parts of the country, but especially in Minnesota. These men all took part in all activities of the society. Among them were Drs. C. A. Wheaton of Saint Paul, F. A. Dunsmoor of Minneapolis, Dr. Millard, who was Dean of the new Department of Surgery at the University, Dr. Arnold Schwyzer of Saint Paul, Dr. W. W. Mayo and his two famous sons, Drs. W. H. and C. A. Mayo of Rochester, all of whom were prominent on society programs and most of whom served as its president. In this connection, it is also interesting to note that a Minnesota surgeon, Dr. Justus Ohage of Saint Paul, performed the first successful operation in America for removal of the gall bladder.

The first mention of x-ray on any society program came in 1896. Dr. A. A. Law of Saint Paul showed the first shadowgram that year and, in 1897, appeared to be the only one in the state using the new kind of picture as an aid to diagnosis.

Membership in the society increased steadily from 119 in 1869 to 357, when Dr. Wheaton reviewed the history of the organization as president in 1889. The burning question of whether or not to admit women to membership had been discussed from time to time, with varying degrees of sarcasm and downright horror, from the year 1873 when Dr. Harriet E. Preston of Saint Paul had applied. By 1880, however, resistance had been worn down and women were admitted by a vote of thirty-nine to three.

The society continued, year after year, to affirm its adherence to the Code of Ethics of the American Medical Association. Advertising by regular practitioners had ceased fairly early; and when a member was expelled, for the first time in the history of the state society in 1891, it was for advertising. Fee splitting was also distressing the ethical and pressing for action. A resolution explicitly condemning it was passed in 1900, but it continued to plague the officials of the society.

As early as 1893, a yearly salary of $100 each, was paid to the secretary and the treasurer of the association and the dues skyrocketed in that year from $2.00 to $3.00 a year, though they were not to remain at that inflationary figure for long. In that year, also, there were county and district medical societies covering the entire state, but they were called "auxiliaries" to the Minnesota State Medical Society, and the ties between them and the state society were extremely loose.

Officers were inclined to watch in despair the successes of irregular medical cultists with the Legislature, powerless because of the lack of unity among the doctors, though the latter were far more numerous in the state.

A movement was already on foot, however, which provided for real unity and the basis for medical organization as it exists today. The American Medical Association had drawn up a constitution and by-laws for all state and county medical societies which created a close, functional relationship, at all levels of organization, and which was to become the envy of all other professional organizations. This new constitution had already been accepted in a number of eastern and southern states and was presented to the Minnesota society, officially, for the first time in 1902. Its introduction coincided with a meeting of the American Medical Association in Saint Paul. A mild preparatory measure was all that was taken at the 1902 meeting. In 1903, however, everybody seemed to be ready for the conversion and the state and county society relationship, as we know it today, came into being. Overnight, the county, instead of the state organization, became the basis and the most important unit of the state and national organization. The state was parcelled off, at the same time, into eight councilor districts with an elected representative from each making up an executive body called a Council. Each county and district society was to elect representatives, according to its size, to a House of Delegates which should meet at least annually, determine policies and elect officers. All members were to be accepted or rejected as the county unit saw fit and county and district society members automatically were accepted as members of the state and national organization.

The advantages of this close-knit organization seem so obvious that it is difficult, now, to understand how much spadework was necessary to make it a working reality. Some members of the "auxiliary" societies were especially stiff-necked about merging their interests with others and were heard to murmur, inevitably, about "a little group" that was running things in the state society. There was, however, the scandalous situation, recognized by all, whereby a man who had been refused membership in his home society might be accepted by a distant society, which was unaware of his past, and so reap the advantages of acceptance by organized medicine.

Dr. J. N. McCormick of Bowling Green, Kentucky, chairman of the American Medical Association's committee, sparked the campaign for the new organization. He was ably seconded by many distinguished Minnesota doctors, among them, Dr. Arthur Sweeney of Saint Paul, who had served as chairman of the Society's Committee on Legislation, and who spoke feelingly of the political weakness of the profession in the state. "We are one in our antipathies," he had remarked with some bitterness in an address before the society in 1902, "and there our unanimity ends. We have no real unity of effort and, without that, our prejudices only serve to belittle us and expose us to the ridicule of the public. Our prosecution of the illegal practitioner is so ill-directed and so tinged with personal feeling as to take on the appearance in the public eye of petty persecution."

When the new plan was accepted in 1903, a real burden was placed upon the shoulders of the new councilors. Upon them, chiefly, rested the responsibility for bringing their county and district societies into the new scheme, of extending membership, of organizing new units and of explaining the objectives of the new movement.

Because the job was done well and with astonishing speed, considering the difficulties, those first councilors deserve credit and recognition. Their names and districts were as follows: First District, Dr. Eugene A. Hensel, Alexandria; Second District, Dr. Walter Courtney, Brainerd; Third District, Dr. William S. Fullerton, Saint Paul; Fourth District, Dr. Frederick A. Knights, Minneapolis; Fifth District, Dr. Harper M. Workman, Tracy; Sixth District, Dr. Alfred E. Spalding, Luverne; Seventh District, Dr. Franklin A. Dodge, Le Sueur; Eighth District, Dr. Adolph O. Bjelland, Mankato. Dr. Fullerton of Saint Paul was the first chairman.

The constitution of 1903 remains the basis of organization today, though it has been altered a little, from time to time, to meet the altered conditions of fifty years. Membership has expanded from about 400 in 1903 to 3,223, as of January, 1953. The modest budget of $4,330 has substantially increased, but so have the dues, although they were reduced to $2.00 again in 1903. Dues were to be increased only by a four-fifths vote of the House of Delegates, according to the new constitution. The program of the society, called an "association" after 1903, has expanded almost beyond the recognition of those early stalwarts, but not beyond their imagination. In their enthusiasm, they foresaw great developments for their organization when their membership should be unified.

That unification has been accomplished to a degree which is the admiration of most people, though it is viewed with alarm by those who oppose the program and aspirations of organized medicine in the United States.

The program has reached out in all directions to implement the interests of medical men. It stretches far beyond medical matters, to the education of the public, as well as the education of the physician; and to the maintenance of high standards in teaching, practice, and hospital care. It stands in the front rank of all movements calculated to improve the public health.

This expansion soon made the part-time secretary, who carried on his practice in addition to the work of the association, impractical. Dr. Thomas McDavitt of Saint Paul accepted the job on a part-time basis in 1900. He was succeeded by Dr. Earle Hare of Minneapolis and, later, by Dr. Carl B. Drake of Saint Paul, in 1921. In 1925, Dr. E. A. Meyerding took over the post in connection with his duties as executive secretary of the Minnesota Public Health Association. That arrangement was outgrown, too, and in 1938 the Minnesota State Medical Association established its own headquarters, which have since been greatly expanded, in the Lowry Medical Arts Building in Saint Paul. In that same year, Dr. B. B. Souster became secretary of the organization, with a full-time executive secretary, Mr. R. R. Rosell, as aide and operating head of the organization. This last move was in

MEDICAL SCHOOLS AND MEDICAL EDUCATION OVER THE PAST CENTURY

HAROLD S. DIEHL, M.D.
Minneapolis, Minnesota

THAT GOOD medical practice depends primarily on sound medical education was officially recognized by the medical profession of this country more than a century ago when the newly established American Medical Association set the improvement of medical education as its primary objective. Achievements since that time have been truly phenomenal, so that today medical education in America is recognized as outstanding in the world.

Pioneer Medical Education

A century ago medical education in this country was truly in its infancy. The medical schools of the University of Pennsylvania, of Columbia University and of Harvard University, were established prior to 1800. However, only 20 other medical schools of the 72 currently functioning in this country were in existence a 100 years ago, and of these only three, Washington University in St. Louis, Western Reserve University in Cleveland and the University of Michigan, were in the mid-west. None was in the far west.

Since 1903	18
Total	72

The lack of medical schools in the west, or rather of medical schools which have persisted, does not mean that prior to 100 years ago there was no medical instruction in these great areas. In those early days medical education like everything else was truly on a free enterprise basis and completely unregulated. Any physician who wished to do so could set himself up as a preceptor for the training of medical practitioners. And practically any group of physicians could start a medical school if they so desired, and many did.

Unquestionably many preceptors and many physicians who organized medical schools were sincerely and conscientiously attempting to meet the need for medical instruction in a frontier country. There is an amusing story of the preceptor of this era who told three or four students who had been studying with him for several years that their training was completed and that they were now ready to undertake the practice of medicine on their own responsibility. He explained that he had done the best he could for them. He had made his books available for their study and he had tried to teach them all that he could about the practice of medicine. But, he said, "There are two things about this that trouble me. One is, that I am sure that half of what I taught you is wrong. This troubles me, but the other troubles me more. That is, I am not sure which half it was."

Unfortunately, not all the preceptors nor all the physicians who organized medical schools were motivated by altruism. Some saw rather the obvious advantages of having the services for several years of devoted unpaid and willing assistants; some coveted the prestige of being known as a professor of a medical school; and some profited substantially from the fees paid by the students for their instruction.

Concerning this era of medical education, Abraham Flexner in his epoch-making report on Medical Education, said:

> "A third type (of medical education), already so discredited as to have become absurd, is associated with the new world, where an unprecedentedly rapid expansion of population over an enormous territory created a demand for doctors long before there existed facilities for their proper training or means for their support. The inevitable happened. Loose and shifting bands of practicing physicians calling themselves a faculty, tried to impart, chiefly by lectures, to heterogeneous uneducated groups of students the empirical knowledge—sound and unsound—which they themselves possessed. First and last, American towns have produced over 400 such medical schools. . . . Pioneer conditions explain how the physicians of that day came to manufacture by the thousands doctors who had small chance to acquire either knowledge or skill. Proprietary medical schools of the United States were mainly private businesses. A few of them—Harvard and Pennsylvania—for example, were in name and in law university departments, but lacked university standards, ideals and facilities."[3]

"During this era of proprietary medical education the

Dr. Diehl is Dean of the Medical Sciences, University of Minnesota.

> standards of admission were so low that Dr. Charles W. Elliott remarked, upon becoming president of Harvard in 1869, that anyone who chose could come in off the street and enter the Harvard School of Medicine. The medical curriculum consisted of courses of lectures running through four months of the year, repeated year after year. President Elliott proposed to substitute instruction which would be progressive and continue for a period of nine months each year instead of four. He further suggested that no candidate should obtain a degree without passing a strict written examination in all the chief departments of instruction, instead of five out of nine as had been previously required. The head of the Medical School was so disturbed at the changes recommended that he declared that the young president was about to wreck the school, and that it would cease to exist in a year or two if such revolutionary reconstruction were allowed. 'He actually proposed,' said this professor, 'to have written examinations for the degree of Doctor of Medicine. I had to tell him that he knew nothing about the quality of Harvard Medical students. More than half of them can barely write. Of course they can't pass written examinations.'
>
> "At the very beginning of his Harvard presidency, Dr. Elliott began the struggle to make the Harvard Medical School a general university department in the true sense. Similar steps were subsequently taken elsewhere. The movement did not, however, gain momentum until in the last decade of the century when Johns Hopkins Medical School, a university faculty in approximately the German sense, made a success in Baltimore."[2]

In the upper Mid-West, the first charter granted to a medical school seems to have been in 1848 when the Madison, Wisconsin, Medical College was incorporated. This school never admitted any students, but later in the same year "a branch" of this college was opened at Rock Island, Illinois, under the name of the Rock Island Medical College. At the opening of this school Dean Knapp announced:

> "No honor could be more congenial to my feelings, for since enduring some fifteen years of toil in the profession in Illinois to find myself at last in this El Dorado of the flow'ry West, on the banks of a river lovelier than the "Blue Moselle," presiding as accoucheur at the birth of a new institution of medical learning, pure, promising, and undefiled by perfidy, comely in every feature and limb, matchless, indeed at her birth, is to me a source of more unalloyed happiness than I could enjoy were I elected to the Chief Magistracy of a State."[4]

In spite of this oratory on the part of the dean, the school remained at Rock Island for only one term of three months, at the end of which it conferred two Doctor of Medicine degrees.

The Rock Island school moved next to Davenport, Iowa, where it was named the College of Physicians and Surgeons of the Upper Mississippi. Within a few months it moved again. This time to Keokuk, Iowa, where it obtained affiliation with the State University of Iowa. In this location it functioned for more than fifty years, until 1908, when it merged with Drake University at Des Moines. Meanwhile, in 1869, the State University of Iowa organized a College of Medicine in Iowa City. Finally, in 1913, the Drake School merged with the school at Iowa City to give the state a single strong medical school.

In Wisconsin, a second medical school was organized in Milwaukee in 1850 under the charter of the infant State University. However, this school like the one in Madison never opened its doors to students. Four years later, the Regents of the University of Wisconsin created a department of medicine, but it was not until 1907 that the first class was admitted for instruction in the basic medical sciences and not until 1925 that the clinical years of the medical course were added.

Beginnings of Medical Education in Minnesota

In Minnesota, a medical school was authorized by the territorial legislature of 1851 and by the state legislatures of 1868 and 1872. It appears, however, that the first effort in organized medical education in Minnesota was the establishment in 1871 of "The Saint Paul Medical School—Preparatory." Concerning these early days, Dr. J. A. Stewart of Saint Paul wrote:

> "My earliest recollection of anything that even simulated organized medical instruction in Saint Paul was when, in 1868 or 1869, the students, reading in the different doctors' offices, met in the second story of the little stone dead-house, which stood to the left of the original building of St. Joseph's Hospital. It contained a table, chairs, and the inevitable skeleton. Dissections of amputated limbs, et cetera, from the hospital were made there, and regular instruction was given by members of the staff, of whom I recall Dr. D. W. Hand and my father."[4]

The President of the Saint Paul Medical School Preparatory was Dr. Alexander J. Stone. The course of study was four months in length and was not designed "to represent or to take the place of the work of a regular college, but to prepare the students for better understanding of the lectures they would hear in the college course." The hours of instruction were six a day, from 3:00 to 10:00 p.m.

Also, in 1871, a second medical teaching enterprise was organized in Minnesota as the Winona Medical School, Preparatory. "Both of these preparatory schools continued their missionary efforts until 1878, neither of them undertaking to do more than the self appointed task of bettering the educational status of the profession; graduating no students; conferring no diplomas; boasting no alumni; but remembered by many a physician whom they helped in their unpretentious fashion, for better understanding of and a better preparation for his life work."[4]

Dr. Perry H. Millard

Upon the discontinuance of the Saint Paul Preparatory Medical School a group of the faculty organized the Saint Paul Medical School, "which had for its college building rented rooms over a saloon on Third Street, opposite and near the Metropolitan Hotel, in Saint Paul." The following year this school became the medical department of Hamline University. Initially the requirement for a degree was a course of study of two years of twenty-six weeks each. Within a few years, however, the length of the course was extended to three years.

This college was officially discontinued in 1881 when its faculty joined with other Minneapolis and Saint Paul physicians to organize the Minneapolis College Hospital. This occupied "a part of the magnificent building known as the old Winslow House, situated in east Minneapolis." The length of the college term was first announced as eighteen weeks. It was later lengthened to twenty-two weeks.

The University of Minnesota Medical School

The Regents of the University of Minnesota took the first step in the establishment of a medical school on January 5, 1883, when they authorized the organization within the University of a college or department of medicine. This department of medicine, according to the plan prepared and submitted by Dr. Charles N. Hewett, then state health officer, Dr. William H. Leonard, a prominent Minneapolis physician, and President William W. Folwell of the University, initially was a purely examining body, having no teaching functions. The legislature in this same year passed an Act to Regulate the Practice of Medicine in the State of Minnesota. This act required that physicians be licensed in order to practice within the state and conferred upon the faculty of the Department of Medcine of the University the functions of an examining board.

Also, in 1883, there was organized in Minneapolis another private medical college under the name of the Minneapolis College of Physicians and Surgeons. Twelve years later, this college became the medical department of Hamline University.

On April 7, 1887, a committee of physicians urged the Board of Regents at the University to establish a teaching school of medicine, and on January 28, 1888, the Regents accepted the offer of the trustees of the Minnesota College Hospital and the Saint Paul Medical School to surrender their charters and to use their properties for a period of five years. On March 8 of the same year, the Regents accepted the offer of the trustees of the Minnesota Homeopathic Medical College to surrender its charter to the University of Minnesota. These three colleges were combined, and the College of Medicine and Surgery of the University of Minnesota was established by the Board of Regents on March 16, 1888.

Concerning the amalgamation of these independent medical colleges into a state university medical school, Dr. Cyrus Northrop, then President of the University, in an address delivered in 1908, stated:

> "The credit for organizing this college, by combining the best men of the various independent medical colleges into a new faculty of the university, and securing the retirement of independent colleges from the work of teaching, so as to give the Medical College of the University a practically clear field, belongs to Perry H. Millard, the first Dean of the College. The pertinacity,

firmness, skill and tact displayed by Dr. Millard were wonderful, and success crowned his efforts at last, although I had often thought he would fail."

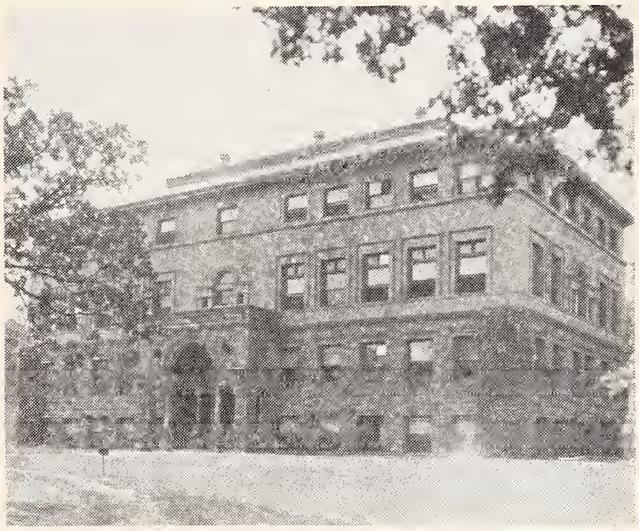
Twenty years later the other medical school in the state, which had been affiliated with Hamline University, merged with the Medical School of the State University. Since that time the presidents of the University, the members of the Board of Regents, with the aid of the deans and the medical faculty, have steered the school on an unwavering course toward the goal of the best in medical education and, through the physicians educated in the school, the best in medical service for the people whom they serve.

The Medical School was conducted until 1893 in a small building near Asbury Hospital in Minneapolis. In these early days, the school lacked laboratories and clinical facilities of its own and all of its twenty-nine faculty members had to earn their livelihood in the private practice of medicine.

The first medical building on the University campus was constructed in 1893 with some funds personally advanced by Dean Millard. This building has been occupied by the College of Pharmacy for the past forty years. Two years later a Medical Science Building, now known as Wesbrook Hall, was constructed to increase the facilities of the Medical School.

In 1912, Millard Hall, the Institute of Anatomy, and the Elliott Memorial Unit of the University Hospital were constructed south of Washington Avenue to form the first units of the new medical campus. Subsequent additions to the facilities of the Medical School include the George Chase Christian Memorial Cancer Hospital and Institute and the Todd Eye, Ear, Nose and Throat Hospital, constructed in 1924; the Eustis Children's Hospital and the University Hospitals Out-Patient Department constructed in 1929; the Psychopathic Hospital addition to the University Hospital in 1937; the Variety Club Heart Hospital in 1951, and the splendid Mayo Memorial addition now under construction.

The entrance requirements of the Medical School were originally a high school diploma or "equivalent preparation as evidenced by a special test." In 1899, the entrance requirements were raised to equal those of the "Arts College." These requirements were further increased in 1902 to one year of collegiate work; in 1908 to two years, and in 1939 to a minimum of three years of college study, with preference given to applicants for admission who have completed the requirements for an academic degree. The length of the medical course was initially three years but was increased to four years in 1895. A fifth or intern year was made a requirement in 1916.



The first medical building erected on the University Campus. Built in 1893, it is still in use. (See text.)

Minnesota—A Strong Medical School

The basic essentials for a strong medical school, beyond reasonably adequate facilities and a sound administrative organization, are a strong and energetic faculty, an able and interested student body, and adequate support. In all of these areas, Minnesota has fared well.

The faculty of the important developmental years of the school included such distinguished medical educators, teachers and scholars as the following:

In Anatomy: Dr. Clarence M. Jackson, Dr. J. B. Johnston, Dr. Thomas G. Lee, Dr. Andrew T. Rasmussen, Dr. Charles Erdmann, Dr. Hal Downey, Dr. Richard E. Scammon.

In Bacteriology: Dr. Winfred P. Larson, Dr. Arthur T. Henrici, Dr. Robert Green, Dr. Halvor Halvorson.

In Pathology: Dean Frank F. Wesbrook, Dr. Harold E. Robertson, Dr. E. T. Bell, Dr. Benjamin J. Clawson.

In Pharmacology: Dr. Arthur D. Hirschfelder, Dr. Edgar D. Brown.

In Physiology: Dean E. P. Lyon, Dr. Richard Olding Beard, Dr. Frederick H. Scott.

In Physiological Chemistry: Dr. Jesse F. McClendon, Dr. George Burr.

In Medicine: Dr. Charles Lyman Green, Dr. George D. Head, Dr. Leonard V. Rowntree, Dr. S. Marx White, Dr. Henry L. Ulrich, Dr. John P. Schneider, Dr. Hilding Berglund, Dr. Hobart A. Reimann, Dr. George E. Fahr, Dr. Moses Barron.
In Obstetrics and Gynecology: Dean Parks Ritchie, Dr. Alexander J. Stone, Dr. Jennings C. Litzenberg, Dr. John L. Rothrock, Dr. Fred Adair.
In Ophthalmology and Otolaryngology: Dr. Frank C. Todd, Dr. William R. Murray, Dr. Frank E. Burch, Dr. Horace Newhart.
In Pediatrics: Dr. Julius P. Sedgwick, Dr. Frederick W. Schlutz, Dr. Walter R. Ramsey, Dr. Frederick C. Rodda, Dr. James T. Christison.
In Surgery: Dean Perry H. Millard, Dr. Charles A. Wheaton, Dr. Frederick A. Dunsmoor, Dr. James E. Moore, Dr. Archibald MacLaren, Dr. Alexander R. Colvin, Dr. J. Frank Corbett, Dr. Arnold G. Schwyzer, Dr. Arthur A. Law, Dr. Harry P. Ritchie, Dr. Arthur C. Strachauer.
In Urology: Dr. Franklin R. Wright
In Orthopedic Surgery: Dr. Arthur J. Gillette, Dr. Emil S. Geist.
In Psychiatry and Neurology: Dr. Arthur S. Hamilton, Dr. Arthur A. Sweeney, Dr. J. Charnley McKinley, Dr. Ernest M. Hammes.
In Radiology: Dr. Robert G. Allison.

These and other devoted teachers and scholars laid the basis for and patiently developed a strong medical school which our present able faculty is carrying forward with distinction.

Medical students at the University of Minnesota have always been an able, earnest and hard working group. In recent years, the number of applicants has far exceeded the number of positions available in the class. The result has been the admission of highly selected groups of students who have made excellent records in the Medical School and in practice of their profession.

Support for the activities of the Medical School has been provided by the Legislature as part of the general University appropriation. This has been reasonably liberal in relation to the resources of the state. In recent years, however, the per student budget of the University of Minnesota Medical School has been below that of our neighboring states of Iowa, Wisconsin and Michigan. Buildings for the Medical School have been constructed in considerable part by private gifts and bequests, and four professorships have been endowed by private funds. These private contributions have been invaluable in the development of the Medical School, but the Medical School will always be dependent for basic support upon state appropriations.

What of the Future?

The Medical School of the University of Minnesota is today an institution in which its alumni, the medical profession and other citizens of the state can justifiably take pride. It is stronger than ever before, not only in medical teaching, but also in medical research—the pioneering scientific work which keeps an institution alive and progressive and brings distinction to its name. With the new buildings that are under construction, facilities will be vastly improved. Urgently needed also are a medical library building and the remodeling and enlargement of Millard Hall and the Anatomy Building. These will doubtless follow in due time. From the State of Minnesota will always come plenty of able medical students. Adequate financial support to meet increasing cost is currently a major problem, but with the continuing interest and support of the medical profession and the citizens of the state, there is every reason to hope that the necessary funds will be provided in the future as they have in the past. The total prospect, then, should be for continuing progress and distinction in medical education, medical research and medical science for the University and for the State of Minnesota.

HEALTH EDUCATION

Health education of the public . . . is often considered the responsibility of organized voluntary and official community agencies. Of course, it is also the physician's personal responsibility. He certainly should educate his patients and their families and do what he can as part of the community program. Health education methods have changed materially in recent years, with much greater emphasis on community organization and on helping the people to help themselves.—Hugh R. Leavell, M.D., *The New England Journal of Medicine,* December 4, 1952.

EIGHTY YEARS OF PUBLIC HEALTH

NETTA WILSON, M.A., M.S. and ALBERT J. CHESLEY, M.D.
Saint Paul, Minnesota

> "I am happy to be able to report the organization of a State Board of Health, by the Legislature of Minnesota, in accordance with the request of this Association (State Medical Association) . . . The Board have already begun their work, encouraged by the cordial co-operation of the entire profession."

THUS did Dr. Charles N. Hewitt, first secretary of the Minnesota State Board of Health, report the creation of the board in 1872. The Minnesota board was the third to be set up in the United States. Massachusetts had created a state board of health in 1869 and California in 1871.

Throughout more than eighty years, the "cordial co-operation" of the medical society and the board of health has continued. The act creating the board provided that the Governor should appoint seven physicians as members. In 1894, a legislative amendment increased the board to nine members who were to be "persons trained in sanitary science." This change opened membership to persons other than physicians, but there have always been more physicians on the board than members of any other profession, and the board of health roster through the years contains many of the most illustrious names in Minnesota medicine.

Throughout its history, the Minnesota State Board of Health has been "remarkably free of political influence." There have been only four state health officers—Dr. Hewitt, 1872-1897; Henry M. Bracken, 1897-1919; Charles E. Smith, 1919-1921 (he died in the latter year); and Albert J. Chesley, 1921 to the present.

The Age of Discovery

The first quarter-century of the board's history constituted an age of discovery. The years from 1872 to 1897 were marked by tremendous advances in public health, despite lack of funds and limited scientific knowledge and equipment. Dr. Hewitt was alert to every new development, but at the same time always cautious in using only proved methods of disease control. From 1872 until 1893, he carried on the public health work of the state from his own small office in Red Wing, which served as administrative headquarters, laboratory, and office for his private practice. His initial salary as part-time state health officer was $200 a year, his entire appropriation $500 a year. He gave generously of his own time and his own funds to the promotion of public health. In 1893 the board's offices were moved to St. Paul, and since that time they have been located in one or both of the Twin Cities.

Chief reason for the establishment of all the early boards of health was the appalling prevalence of acute communicable diseases. In the first year of Dr. Hewitt's administration in Minnesota, there were more than a thousand cases of smallpox in the state, with 250 deaths. Typhoid fever—a disease then characterized as "of miasmatic origin"—was "very rarely absent from the state." Cholera and yellow fever were "epidemic and very fatal." Cerebro-spinal meningitis occurred widely and frequently. In the diphtheria epidemic of 1879-80, hundreds of infants and children died.

One of Dr. Hewitt's major control measures was the promotion of smallpox vaccination. In 1890, he established at Red Wing a station for the production of pure vaccine and continued to operate it for the next seven years. From this station he distributed vaccine at cost to physicians throughout Minnesota and also to the United States Army in the Department of the Dakotas. At a time when the bacterial cause of communicable disease was still regarded as a debatable theory, he made many practical observations in the epidemiology of such diseases.

In 1873, Dr. Hewitt set up a small improvised laboratory in his office at Red Wing. His early laboratory studies were limited to chemical analyses of food, milk, water, and kerosene. He continued to do this work until the state Dairy and Food Commission was created in 1885. In 1890, at his own expense, he spent six weeks of intensive study in Europe. In England and Germany, he investigated the most up-to-date knowledge of diphtheria, and in France he worked with Louis Pasteur on the control of rabies. On his return to Minnesota, he developed "one of the first bacte-

Mrs. Wilson is Senior Health Information Consultant and Dr. Chesley is Secretary and Executive Officer of the Minnesota State Department of Health.

riological laboratories concerned with human infections west of the Alleghanies." The Minnesota laboratory was also one of the first to perform the Widal test for typhoid. In 1893, the laboratory was moved to the old Mechanics Arts Building on the campus of the University of Minnesota. Dr. Hewitt did sputum examinations for suspected tuberculosis in 1891, and in 1894 he offered this service on a statewide basis.

Dr. Hewitt's services to the medical profession and the people of Minnesota were not limited to his work for the State Board of Health. He promoted the creation of an examining board for all practitioners of medicine in the state, thus freeing Minnesota from medical quacks long before their activities were suppressed in many other areas. His appointment as professor of public health at the University in 1873 was "probably the first . . . in the country." He held the post for twenty-eight years, during which he inaugurated the physical examination of all students entering the University—a novel procedure for that time. In 1891, at Dr. Hewitt's request, the federal Marine Hospital Service, forerunner of the U. S. Public Health Service, sent to the Minnesota state board of health the first notification of a case of infectious disease in a traveler bound for Minnesota. This service has continued ever since without interruption, and a similar arrangement has been made with the government of Canada.

From its earliest days, members of the Minnesota State Board of Health understood the importance of environmental sanitation. In 1875, Dr. Hewitt began the examination of samples of water, milk, and foods. In 1876, the board was hiring the services of a sanitary engineer "as needed" in order to help correct some of the extremely bad sanitation practices of the time. Dr. Hewitt described the water supply and sewage disposal systems in public institutions as "a disgrace to the state" and never ceased to urge upon state legislators and the public the need for improvement. In 1885, the Legislature empowered the state board of health to prevent the pollution of domestic water supplies.

Also in 1885, the State Board of Health was charged with the control of contagious diseases in animals. In 1897, the board appointed as head of its veterinary department Dr. H. M. Reynolds, who was a doctor of medicine as well as a veterinarian. He became the first secretary of the Live Stock Sanitary Board when it was established in 1903 and took over animal disease work in the state.

Such was Dr. Hewitt's prestige that he was able to attract to Minnesota some of the leading young pioneers in public health work in the nation. One of these was Dr. Frank Fairchild Wesbrook, who "was to add greatly to public health science in Minnesota." First employed as a bacteriologist in 1895, he remained in charge of the board of health laboratory until he was made dean of the university medical school in 1910. He served also as professor of bacteriology and pathology at the university and as a member of the state board of health. He was succeeded as laboratory director by another Minnesota pioneer, Dr. Orianna McDaniel.

Because of the prevalence of rabies in Minnesota, Dr. Hewitt on his return from Europe in 1890 had recommended the establishment of a center for diagnosing the disease in human beings and for giving the Pasteur treatment. It was not until 1907, however, that the board was finally able to obtain funds for the establishment of a Pasteur Institute, and Dr. McDaniel was placed in charge of it. The institute continued to operate until 1921, by which time antirabic vaccine was readily available for use by private physicians.

The Age of Development

The second quarter-century of public health in Minnesota saw the development and extension of the pioneer work begun by Dr. Hewitt and his associates. Those years also included the first world war and the attendant disruption of civilian public health services due to the absence of more than one-third of Minnesota's physicians and nurses on military service.

The war, however, was not without certain favorable effects on public health. For one thing, it brought to light the previously unsuspected prevalence of venereal disease. The Governor of Minnesota appointed a Social Hygiene Commission to assist in control measures. Their program was promptly co-ordinated with that of the state board of health, which in 1918 appointed Dr. H. G. Irvine to direct a comprehensive control program financed by emergency state and federal funds. This was the first occasion when federal funds were given to the states for a specific public health program. The wisdom of the innovation was doubted by some members of the medical profession, but whatever misgivings they may have had were resolved by Dr. Irvine's handling of the program. He worked in the closest possible co-operation with the medical association, and put into practice his belief that as soon as possible the state board of health should withdraw from the treatment field and leave it to private practitioners, while continuing to give advice and help to all physicians who might need it. For thirty-five years this program has been so effectively carried out that Minnesota has had for a long time one of the lowest venereal disease rates in the nation.

Another notable advance during the age of development was in tuberculosis control. In its pioneer days, Minnesota somehow gained a reputation as "an asylum for consumptives." The result was exceptionally high death rates from tuberculosis. The highest death rate, 119.7 per 100,000 population, was recorded in 1911. Contributing to this high death rate was the great prevalence and fatality of tuberculosis among the state's Indians. At Dr. Bracken's request, the U. S. Public Health Service in 1912 conducted a thorough survey of communicable diseases among Indians. The findings of this survey were very valuable in obtaining support for future public health programs for the Indians.

In 1907, a ninety-bed state tuberculosis sanatorium was opened at Walker, especially for the care of early cases. Dr. Walter J. Marcley was its first superintendent. A legislative act of 1909 provided for the creation of county sanatoria. During the period since then, fifteen have been established and have rendered a valuable service in isolating thousands of cases and restoring many of them to health.

A State Tuberculosis Association was organized in 1906, and from then until now has promoted state-wide public education about tuberculosis and has worked with the state board of health in many other ways for control of the disease.

A highly significant factor in the reduction of tuberculosis and other health problems was the development of public health nursing. Since the early days of Dr. Hewitt's administration, the need for such nurses had been stressed by state and local health officers. A few nurses were employed in various sections of the state, but there was no provision for supervising or co-ordinating their work. In 1916, the State Board of Health authorized the employment of a state superintendent of nurses, but no funds were available to carry out the provision. In July, 1918, Miss Frances Brink was employed "to correlate the work of community nursing." This turned out to be a most timely move, for the influenza epidemic struck the state less than three months later, coinciding with a high incidence of poliomyelitis and several disastrous forest fires. This desperate situation inspired many communities to employ public health nurses. For a time, there were approximately seventy-five in the field under Miss Brink's supervision. No money was available to continue the state program after the epidemic subsided, but the need had now been recognized by the medical profession and the public. Despite many setbacks, public health nursing has progressed steadily to the position it now holds as an indispensable aid to practicing physicians.

Although epidemiology had been a major concern of all health departments since their beginning, it is believed that the term "epidemiologist" was first used in Minnesota in 1909, when the title was given officially to Dr. Hibbert W. Hill. A division of epidemiology was established by the State Board of Health on January 1, 1910.

In 1910, there were 688 deaths from typhoid fever in Minnesota. Chlorination of water supplies was started in that same year, after which typhoid showed a progressive decrease. Identification and control of chronic carriers of typhoid germs through epidemiological and laboratory services has been consistently followed since January 1, 1913.

In 1915, 300 stations for the distribution of diphtheria antitoxin were established all over the state. This move, followed in 1926 by the first diphtheria immunizations, contributed much to the control of the disease. Minnesota was one of the first states where two successive negative nose and throat cultures were required before a diphtheria patient could be released from isolation.

From 1917 until 1921, the State Board of Health was responsible for the follow-up care of persons crippled by poliomyelitis. No treatments were given other than aiding in the adjustment of braces and other appliances. "Polio teams" from the health department worked with local physicians and public health nurses to help prevent or lessen disabilities suffered by children who had polio paralysis. The board of health purchased one of the first Drinker respirators and placed it in the University hospital for treatment of polio cases.

It was during this period of development that the board of health began to decentralize its services. One most important move in this direction was the establishment in 1905 of a branch laboratory in Duluth, with Dr. E. L. Tuohy as its director. This laboratory is still in operation.

In 1910, Minnesota became eligible on completeness of death reports to be included in the United States registration area, and in 1915 it constituted one of the ten original states comprising the U. S. registration area for births.

The Age of Consolidation

So diversified has the public health program become during recent years—the age of consolidation—that a brief record such as this can do no more than set down a few of the major landmarks of progress since the end of World War I.

Infant mortality rates decreased from 66.1 per 1,000 live births in 1920 to 2.5 in 1950. Maternal deaths decreased from 6.2 per 1,000 live births in 1920 to 0.6 in 1950. One recent development is the increasing attention being given to the prevention of accidents among children and young people. Accidents now rank first as a cause of death in all age groups from one to thirty-five years.

Communicable diseases, which caused a majority of the deaths in 1920, caused only about 5 per cent of all deaths in Minnesota in 1950. More than 75 per cent of the deaths occurring in that year were charged against chronic diseases, chiefly heart disease and cancer. The tuberculosis death rate in 1952 reached the all-time low of 6.6 per 100,000 population.

Before the first World War, Minnesota had a high venereal disease rate. By 1950, this rate was one of the lowest in the nation. Not one baby infected with syphilis was born in the state that year.

In 1918, the State Board of Health employed a physician to carry on work in child hygiene, but the program had to be suspended because of lack of funds. In 1921, the Sheppard-Towner Act made federal funds available to the states for maternal and child health, and Minnesota re-established its program. During World War II, the Minnesota Department of Health handled more than 30,000 cases under the Emergency Maternity and Infant Care program directed by Dr. V. O. Wilson with the "cordial co-operation of the entire profession" and personal advice of Dr. Roger L. J. Kennedy.

Another recent federal-state concern was the Hospital Survey and Construction program, under which the state board of health since 1946 has administered funds to build thirty-eight new hospitals and aid a number of similar projects. This work is carried on by Dr. Robert N. Barr, Deputy Executive Officer, and Dr. Helen Knudsen, Chief of Hospital Services Section.

Chlorination of municipal water supplies has been standard procedure since 1910. In 1945, the Water Pollution Control Commission was established, making it possible for public health representatives of all states located in a particular drainage area to work together for the common benefit of their populations. Since an annual survey and rating system was started in 1946, there has been a steady improvement in the safety of the state's drinking water. A law providing for the virtual statewide pasteurization of milk became effective in 1950. The environmental sanitation program has been extended to include hotels, restaurants, and (since 1951) tourist and children's camps.

Dental health, occupational health, mental health, and health education have all been added to the health department's duties during the age of consolidation.

Although every state health officer has recognized the need for full-time local health services, there have never been sufficient funds or personnel available to establish them. As a temporary measure to decentralize its services, the health department now operates eight district offices, which since 1948 have included all counties in the state. Minnesota still has more than 1,500 local boards of health with part-time health officers, many of them receiving no pay for their public health work.

From its beginnings in 1872, with one part-time executive secretary, the Minnesota State Board of Health has grown until today it employs approximately 300 people. It carries on a program that involves in some way every resident of the state and provides services that aid the work of every practicing physician.

HISTORY OF THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

1851-1952

F. H. MAGNEY, M.D.

Duluth, Minnesota

THE FIRST record of an authorized body being formed to examine physicians in Minnesota is found in the territorial laws of Minnesota for 1851, where Section 5, provided:

> "The medical societies established as aforesaid are hereby respectively empowered to examine all students who may present themselves for the purpose, and to grant them diplomas under the hand of the president and the seal of the society; which diploma shall constitute them members of said society; and it is hereby made the duty of the censors of each medical society carefully and impartially to examine all medical students who shall present themselves for that purpose and report their opinions in writing to the president of the society."

Section 6 of the same law provided·

> "No person shall be permitted to be examined as a candidate for a diploma and membership of any of said societies, unless he shall have arrived at the age of twenty-one years, has at least a good English education, and has studied medicine at least three years with some respectable practitioner and can produce satisfactory evidence of good moral character."

It is interesting to note that the examination fee was $10.00 and an additional amount not exceeding $3.00 could be assessed "for the purpose of procuring a medical library, anatomical cabinet, chemical apparatus, or for the encouragement of useful discoveries in the science of medicine."

The possession of a diploma was not necessary, for at that time it was not a criminal offense to practice without it. It was not until eighteen years later that definite qualifications were required by law when on March 9, 1869, Section 1 of that law provided:

> "That it shall be unlawful for any person within the limits of said state who has not attended at least two full courses of instruction and graduated from some school of medicine either in the United States or of some foreign country, or who cannot produce a certificate of qualification from some state, district, or county medical society, and is not a person of good moral character to practice medicine in any of its departments or perform any surgical operation for reward or compensation or attempt to prescribe medicine or medicines or perform any surgical operation for reward or compensation within the said State of Minnesota."

A penalty of a fine of not less than $50.00 nor more than $100.00 was established for the first offense and for a subsequent offense the foregoing fine and a jail sentence of thirty days. Section 3 of the same law provided that a physician file his diploma in the office of the clerk of the district court in the county in which he resides or keeps his office. One studying with a preceptor was given three years from the commencement of his course of study to comply with the provisions of the law of 1869. This law was repealed on February 24, 1870 by Chapter 47 of the General Laws of Minnesota for that year.

The first State Board of Medical Examiners was created on March 5, 1883 by Chapter 125, the General Laws of Minnesota for 1883. This law provided:

> "The faculty of the medical department of the University of Minnesota shall organize as a board of examiners as herein provided, within three (3) months after the passage of this Act; they shall procure a seal, and shall receive through their secretary applications for certificates and examinations."

This law also provided:

> "That any person practicing medicine in any of its departments shall present this diploma to the examining board for verification of its genuineness. If the diploma is found genuine and the person named therein be the person claiming and presenting the same, the board shall issue its certificate to that effect. If not a graduate, the person practicing medicine in this state shall present himself before said board and submit himself to such examination as said board shall require."

If the diploma was found to be genuine, the Board was permitted to charge a fee of $1.00, but if found to be fraudulent the board was permitted to charge and collect $20.00 from the applicant presenting such diploma. Candidates for examination were required to pay a fee of $5.00. A person was regarded as practicing within the meaning of the Act: "who shall profess publicly to be a physician and to prescribe for the sick or

---

Dr. Magney is President of the Minnesota State Board of Medical Examiners.

who shall append to his name the letters M.D." One who violated the Act was subject to a fine of not less than fifty dollars or more than five hundred dollars or to imprisonment for not less than thirty days or more than one year.

The next change in the laws was on February 28, 1887, at which time Chapter 9 of the General Laws of Minnesota for 1887 increased the State Board of Examiners to nine members and provided that they were to be appointed by the Governor. The Legislature for the first time provided the subjects for which the applicant must be examined. The subjects were: Anatomy, physiology, chemistry, histology, materia medica, therapeutics, preventive medicine, practice of medicine, surgery, obstetrics, diseases of women and children, diseases of the nervous system, diseases of the eye and ear, and medical jurisprudence. The applicant must have attended three courses of six months each. Seven members of the Board had to consent to the granting of a license. The penalty for practicing without a license was stipulated at not less than $50.00 nor more than $100.00, and by imprisonment in the county jail for not less than ten days nor more than ninety days.

In 1895, the Legislature increased the requirements to four full courses of lectures at a school recognized by the Board. This became effective on or after January 1, 1899.

Reciprocity was first recognized by the Minnesota Legislature in 1905. Section 2297 of the General Laws provided that the Examining Board may grant a license to physicians licensed to practice by a similar board in another state.

In 1911, the Legislature authorized the Medical Board to issue itinerant licenses to physicians in addition to their regular license on the payment of a fee of $300.00. However, this authorization being discretionary, the Board does not issue itinerant licenses because the granting of such a license is not in the best interest of the public.

Fee-splitting was first prohibited by law in Minnesota by Chapter 365 of the Session Laws of 1917, the law providing: "It shall be unlawful for any physician or surgeon to divide fees with or to promise a part of his fee to or pay a commission to any other physician or surgeon or person who calls him in consultation or sends patients to him for treatment or operation."

On April 15, 1919, the Legislature provided that the State Board of Medical Examiners may, with or without examination, grant a license to any physician who has satisfactorily passed the examination given by the National Board of Medical Examiners.

In 1927, the Legislature reduced the Board membership to seven and provided that the Council of the Minnesota State Medical Association might make recommendations of three physicians for each position on the new Board. It was at this session of the Legislature that the basic science law was passed. Each physician was required to register during the month of January in each year and to pay to the Board a fee of $5.00 a year for the first two years, and two dollars per year thereafter. The law authorized the State Board of Medical Examiners to expend this money in the enforcement of the Medical practice act and the basic science law. This then marked the beginning of the enforcement of the medical act as we find it today. Another requirement is that each physician must qualify for a basic science certificate as a prerequisite to securing a medical license.

The Board has the duty of examining and registering midwives. They were first registered in 1891, at which time there were 256. The present registration is twenty-one.

Masseurs have been examined and licensed by the Board since 1929, at which time licensing by their own board was discontinued. It had only been in existence since 1927. At that time there were 268 masseurs. At present there are ninety-five.

The 1951 Minnesota Legislature passed a law authorizing the registration of physical therapists, such registration being under the supervision of the State Board of Medical Examiners. At the end of 1952, 107 physical therapists had been screened and registered.

Medical licenses granted during the years 1883 through 1927, prior to the passage of the Minnesota Basic Science law, and those granted after this law was passed are as follows:

	AFFIDAVITS	EXAMINATION	RECIPROCITY	NATIONAL BOARD	TOTAL
1883 through 1927	1,707	3,972	1,257	47	6,983
1928 through 1952		4,965	863	546	6,374
TOTALS	1,707	8,937	2,120	593	13,357

From 1927 through 1952, 2,867 graduates from the University of Minnesota have been licensed.

Since 1883, 614 women physicians have been licensed; twenty-five during the year 1952.

The largest number of physicians licensed in any one year was 420. This was during 1947.

In May 1949, the Board revised its rules and regulations with reference to foreign physicians and waived the previous requirement of full citizenship and decided to admit physicians who are graduates of foreign schools on an individual basis, providing their credentials can be verified and approved. Since that time, eighty-one applicants have appeared before the Board. Of this number, thirty have passed the examination and have been licensed; nine have been authorized to take the examination; twenty-six have been authorized to take a year's graduate training at one of our approved hospitals in Minnesota; one was permitted to continue his postgraduate training at the University of Minnesota; three are pending regarding verification of credentials; one was denied; eight have not been heard from; and three have withdrawn their application. Twenty-two of the applicants are women physicians.

It was hoped that the licensing of these foreign physicians would provide the wanted medical care for less populated areas and small towns. This has not materialized. Of the thirty licensed, only five have located in small towns. Six have joined the medical staffs of Minnesota State hospitals, four are located in Saint Paul, nine in Minneapolis, and six have left the state.

The total number of physicians registered for 1952 is 6,629. Of this number, 4,031 live in Minnesota and 2,598 out of the state.

The question of the shortage of physicians, as usual, is a much discussed question. The public press, particularly, continues to stress the need for training more physicians. However, the mere training of an additional number of physicians will not insure certain localities the services of a resident physician, as economic conditions are also involved.

On April 1, 1950, the United States census showed the population of Minnesota to be 2,982,483; the state ranked eighteenth in the population of the nation and thirteenth in land area. The 1950 urban population in and around Minneapolis, Saint Paul and Duluth, numbered 1,624,914 (54.5 per cent of the state's population) and the rural population comprised 1,357,569 (45.5 per cent).

Minnesota Census (1950)

Towns	*Population*	*No. Physicians (Dec. 31, 1952)*
Duluth	104,511	165
Minneapolis	521,718	1,193
Rochester	29,885	740
Saint Paul	311,349	531
Other towns	2,015,020*	1,402
TOTALS	2,982,483	4,031

*Of this figure, 687,336 are urban, located near Minneapolis, Saint Paul or Duluth.

Ratio of Physicians to Population

1933	1 to 868 persons
1948	1 to 721 persons
1949	1 to 710 persons
1950	1 to 718 persons
1951	1 to 779 persons
1952	1 to 759 persons
1953	1 to 739 persons

Reciprocity has been established with medical boards of thirty states, and an additional twelve on a discretionary basis, making a total of forty-two. National Board diplomates are accepted in Minnesota without examination.

Since the beginning of the legal enforcement program in 1928, which was made possible with funds secured from annual registration, there have been 356 court cases. Out of this number, 319 persons were convicted. Of the thirty-seven non-convictions, fifteen were declared not guilty, fifteen cases were dismissed, two were not indicted by grand jury, three forfeited bail and two defendants died before the case was heard. The majority of these were unlicensed persons, but there were some physicians and surgeons, pharmacists, chiropractors, osteopaths, beauticians and barbers, masseurs, midwives, dentists, optometrists, registered nurses, and embalmers.

There have been 466 physicians investigated; 438 investigations have been made of persons other than physicians and surgeons. These investigations, together with the court cases, have involved abortions, infractions of the medical and basic science law, advertising laws, civil suits, sale of liquor and narcotic prescriptions, failure to reports births and deaths, excessive use of liquor, use of narcotics, fraudulent prescriptions, immorality, and other miscellaneous complaints. Some of the complaints with reference to physicians have come from dissatisfied patients, and it has been found that the physician had not been at fault.

Thirty-four medical licenses have been revoked

MEDICAL JOURNALISM IN MINNESOTA

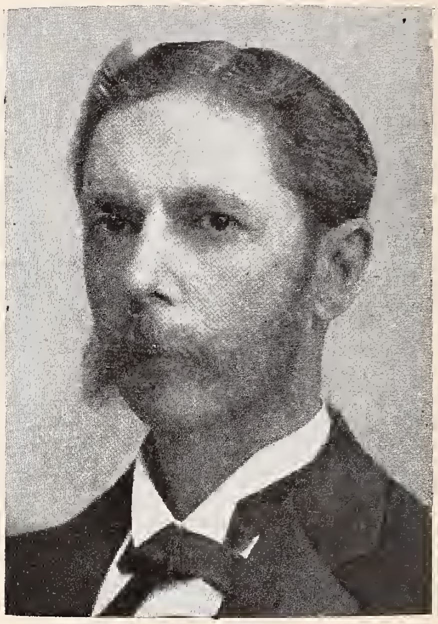
CARL B. DRAKE, M.D.
Saint Paul, Minnesota

THE HISTORY of medical journalism in Minnesota is the story of some fifteen different journals which began publication before 1900. One ceased publication after one issue. Others lasted a few months or years. All went out of existence except the *Northwestern Lancet* which was founded in 1881 by Dr. Jay Owens of Saint Paul, suddenly changed its name to the *Journal of the Minnesota State Medical Association and the Northwestern Lancet* with the appearance of the issue of November 15, 1905, and became the *Journal-Lancet* in 1912. In 1899 the *Saint Paul Medical Journal* made its appearance and continued publication until the Minnesota State Medical Association began its own publication, MINNESOTA MEDICINE, in 1918.

The numerous attempts of the various medical journals to maintain publication failed because of financial reasons—lack of sufficient advertisements and subscriptions—and perhaps a dearth of scientific material.

The first medical journal to be published in the state was the *Minnesota Homeopath* which appeared in Saint Paul in 1859. Dr. George Hadfield, a homeopath, who was the publisher, seemed to be more interested in reaching the public than in serving the profession. Probably only a few numbers appeared.

The first medical journal worthy of the name was the *Northwestern Medical and Surgical Journal* established by Dr. Alexander J. Stone in 1870. Dr. Stone was a native of Maine, had attended Harvard Medical School in 1865-66, as well as the Medical School of Maine and Berkshire Medical College at Pittsfield, Massachusetts. After a trip abroad where he visited Paris, Edinburgh, and London, he practiced with Dr. D. H. Storer in Boston for a short time. In 1869 he came west and settled in Stillwater, Minnesota, which had taken its name from Stillwater, Maine, and had been largely settled by Maine people. His idea of publishing a medical journal having received new impetus at the February, 1870, meeting of the Minnesota State Medical Society *(sic)*, the first issue of the *Northwestern Medical and Surgical Journal* made its appearance June 1, 1870. Dr. Stone was the editor and David Ramaley of Saint Paul, the publisher. In October or November of that year Dr. Stone moved to Saint Paul, which must have greatly facilitated his editorial work. The *Journal* appeared monthly and the subscription price was $3.00 a year or 35 cents a copy.



DR. ALEXANDER J. STONE

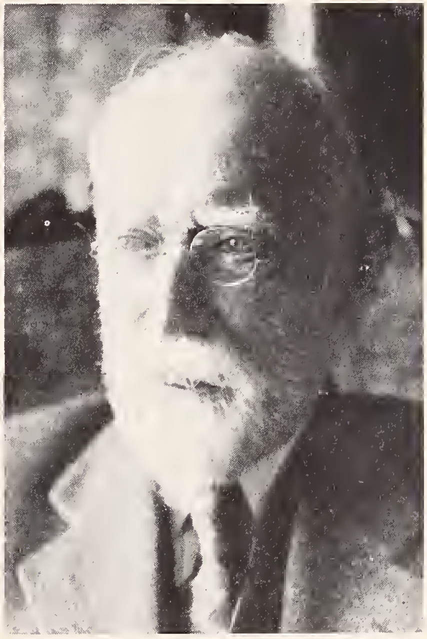
Dr. Stone was not only the first real medical editor in Minnesota; he took part in the first attempt at medical education in the state when in 1870 the Saint Paul School for Medical Education was established with Dr. Stone as secretary. As time went on, Dr. Stone became one of the leading surgeons in the state. His specialty was gynecology and he acquired an extensive and profitable practice. In 1882, when the American Medical Association met in Saint Paul, he was chairman of arrangements, called the session to order and was elected second vice president. In 1887, the University of Iowa conferred upon him the degree of LL.D. In 1872, at the age of twenty-seven he was elected vice president of the Association of American Medical Editors and later president of the association. It was not generally known that Dr. Stone had congenital dislocation of the hips which he successfully concealed by habitually wearing a Prince

Albert. He also developed Dupuytren's contracture of the palms of both hands which, however, did not prevent his operating.

Two years after establishing the *Northwestern Medical and Surgical Journal,* Dr. Stone sold it to Dr. H. C. Hand of Saint Paul who became editor with Dr. H. H. Kimball of Minneapolis as business manager. Somehow, the list of subscribers was lost in the transfer and this must have been a setback. Publication ceased in June, 1874, after four years of publication.

Another early medical publication was called the *Minnesota Medical Mirror* which was published from December, 1881, to March, 1885, in Cambridge, Minnesota, by Dr. N. M. Cook. *The Minnesota Medical Monthly,* a homeopathic organ edited by Dr. Wm. E. Leonard, was published in Minneapolis from May, 1886, to October, 1888. A Dr. Edward Fishblatt published a short-lived journal called the *Minnesota Medical and Surgical Journal* in Minneapolis from August, 1886, to March, 1887. On the title page appeared "Formerly the New York Medical and Surgical Journal." In January, 1889, one issue of the *Minnesota Medical Journal* appeared in Minneapolis under his editorship. In the library of the Ramsey County Medical Society are a few copies of the *Northwestern Medical Journal,* a monthly edited by Dr. E. N. Fishblatt of Mineneapolis, with Dr. W. Elmer Hubbard of Salt Lake City listed as Assistant Editor. It was published in Minneapolis and contained contributions from physicians all over the country. Copies dated November and December, 1891, and January, 1892, volumes 19 and 20, respectively, strongly suggest that this journal was nineteen years old in 1892. Then there was the *Medical Dial* published in Minneapolis by Dr. J. W. MacDonald from December, 1898, to December, 1903, when it was absorbed by the *Northwestern Lancet.* There was also the *Medical Argus,* published in Minneapolis as a homeopathic organ from July, 1890, to January, 1898, under the editorship of Dr. Frank Fisk Cassidy.

The *Northwestern Lancet,* the forerunner of the *Journal-Lancet,* began publication on October 1, 1881, as a semi-monthly. Dr. Jay Owens of Saint Paul was the owner and editor. Dr. Charles B. Witherle of Saint Paul became its editor in November, 1884. In September, 1886, any rights which Dr. Owens might have had in the publication were bought by Dr. Alexander J. Stone for the sum of one dollar. On the title page in 1886 appeared the name of Dr. Stone as proprietor and Dr. Witherle as editor. In 1887 Dr. Stone was listed as editor and Dr. William Davis of Saint Paul as assistant editor. Dr. Davis, in fact, did most of the actual editing of the journal from the time Dr. Stone acquired ownership and the names of both Dr. Stone and Dr. Davis appeared as co-editors from 1891 until 1900. Dr. William Davis was a native of Boston and a graduate of Andover and Harvard (1879). On his graduation from Andover Academy he shipped as a passenger on board a sailing vessel bound for India with a cargo of ice. The voyage was recommended by an oculist as a cure for astigmatism. Strange to relate, the ice reached India after a three months' voyage. Whether the astigmatism was corrected is not known. Dr. Davis came to Saint Paul in 1882 on account of his wife's health. He became one of the leading general practitioners in Saint Paul before he retired in 1939. He passed away in 1947 at the age of ninety-three.



Dr. William Davis

In 1887, William L. Klein, a graduate of Phillips Academy and Cornell College, became business manager of the *Northwestern Lancet.* Besides being business manager he was well qualified to assist in editorial work as proven by the little volume entitled "Why We Punctuate," which he wrote and published in 1897 and which is still authoritative. After graduating from Cornell, he became head of a Normal School at Avon, New York, and later was principal of a school at Woodstock, Illinois. Following that he founded a book publishing company in Chicago.

Dr. William A. Jones

Mr. Klein and Dr. Davis worked together as a most efficient team in the publishing and editing of the *Northwestern Lancet* from 1887 until 1899 when Dr. Davis' place was taken by Dr. Howard Lankester of Saint Paul, who in turn retired in 1901. In the December 15, 1900, issue of the *Lancet,* Dr. Stone editorially announced the severance of his connections with the journal and, in 1901, Dr. William A. Jones of Minneapolis began his editorship, which in association with Mr. Klein as publisher was to last for thirty years. The *Lancet* offices were moved to Minneapolis and Mr. Klein purchased the *Northwestern Lancet* in 1905.

In 1905 the *Northwestern Lancet* changed its name to the *Journal of the Minnesota State Medical Association and the Northwestern Lancet.* The same year it became the official organ also of the South Dakota State Medical Association and remained so until the South Dakota Association established its own state journal in 1948—the *South Dakota Journal of Medicine and Pharmacy.*

In 1912, the journal adopted the shorter title of *Journal-Lancet.* It became the official organ of the North Dakota State Medical Association in 1913 as well as for the Minnesota and South Dakota Associations. In 1918 the Minnesota State Medical Association began publication of its own journal—MINNESOTA MEDICINE—and the *Journal-Lancet* ceased to be the official organ of the Minnesota Association. In 1935, the *Journal-Lancet* became the official organ for the Montana State Medical Association, but in 1948 the Montana Association adopted the *Rocky Mountain Medical Journal* as its official organ.

Dr. William A. Jones of Minneapolis was an outstanding figure in medical circles for many years as a specialist in nervous and mental diseases and as a medical editor. A native of Minnesota, he attended grade schools in St. Peter and received his medical training at the University of the City of New York, graduating in 1881. He immediately became assistant physician at the State Hospital for the Insane at St. Peter, Minnesota. In 1883, he began the general practice of medicine in Minneapolis. After studying in Berlin and Vienna in 1886, he returned to Minneapolis and specialized in nervous and mental diseases. Besides practicing his specialty, he served on the State Board of Health for twelve years, was a clinical professor on the University of Minnesota medical school faculty and edited for thirty years the *Journal-Lancet* and its predecessors which appeared semi-monthly. He also took a very active part in medical organization. His choice of a vacation consisted in a trip to New York where he spent most of his days in his hotel room reading and his evenings at the theater. Fishing and hunting and out-door sports did not appeal to him. When twitted about his bald head, he was once heard to remark that he had early been given the choice of hair or brains and had chosen brains.

In 1929, both Mr. Klein and Dr. Jones gradually turned over the active running of the *Journal-Lancet* to others and since 1931, the year they both died, the editing of the journal has been conducted by an editorial board, with Dr. J. A. Myers of Minneapolis as chairman and Dr. Thomas Ziskin, secretary.

On the basis of Dr. Stone's ownership of the *Northwestern Medical and Surgical Journal* in 1870 and the *Northwestern Lancet* in 1886, the *Journal-Lancet* celebrated its sixtieth birthday in 1931 and its eightieth birthday in 1951, rather ignoring the period of suspended animation which occurred between 1874 and 1880.

The Proceedings of the Minnesota State Medical Association were published in pamphlet form from 1869 until 1905 when the *Northwestern*

Lancet changed its name to the *Journal of the Minnesota State Medical Association and the Northwestern Lancet.* From then on, this journal and its successor, the *Journal-Lancet,* published the proceedings until MINNESOTA MEDICINE took over in 1918.

DR. BURNSIDE FOSTER

The Ramsey County Medical Society began the publishing of the *Saint Paul Medical Journal* in 1899. Dr. Burnside Foster, a St. Paul dermatologist, was editor-in-chief and Dr. H. Longstreet Taylor, the managing editor. On the Editing and Publishing Committee at the start were Drs. Charles A. Wheaton, Angus MacDonald, C. Eugene Riggs, J. W. Chamberlain and Arthur J. Gillette. In 1901, the name of Dr. William Davis appeared on the committee. It was announced that the journal would be published with the collaboration of outstanding physicians of Philadelphia, Boston, Baltimore, New York, Vienna, Milwaukee, Cincinnati, St. Peter, Rochester and Minneapolis.

Dr. Burnside Foster was a native of Worcester, Massachusetts. He attended Yale College and obtained his medical degree from Harvard Medical School in 1886. After a brief tour abroad, he settled in Minneapolis but moved to St. Paul after two or three years. He wrote well and besides editing the *Saint Paul Medical Journal,* he wrote on medicine for lay journals. He was credited with having originated the idea leading to the establishment of the Life Extension Institute by a number of life insurance companies.

In 1916, Dr. Foster became editor emeritus of the journal and Dr. Ernest T. F. Richards assumed the editorship, with Charles E. Smith, Jr., as secretary. An editorial board, one of whose functions was to abstract current literature for the journal, consisted of Wallace Cole, George Earl, Ernest M. Hammes, Carl B. Drake, E. Mendelssohn Jones and Harry B. Zimmerman. The Editing and Publishing Committee was made up of C. Eugene Riggs, Robert O. Earl, H. Longstreet Taylor, Warren A. Dennis and Frank J. Savage.

By the year 1916, the idea of the Minnesota State Medical Association owning its own journal had gained considerable support. In the House of Delegates that year a committee was appointed to investigate the matter. The committee appointed consisted of Dr. E. W. Buckley, chairman, George E. Senkler, R. J. Hill, J. Warren Little and Charles Scofield. The committee was directed to make its investigation and submit its findings to the county societies six months in advance of the next annual meeting of the State Association. At the meeting of the House of Delegates in 1917, Dr. Scofield presented the majority report of the committee signed by all members of the committee except Dr. Buckley, and simply stated that it was deemed inadvisable for the Association to publish its own journal. Dr. Buckley, chairman of the committee, then presented the minority report. He told of having written all the editors of the then existing twenty-eight state journals which represented thirty-three state medical associations; that the twenty he had heard from were doing well and favored the idea of a state association owning its own journal. Thus advertising would be limited to items approved by the Council of Pharmacy and Chemistry of the American Medical Association. He listed some twenty unaccepted articles advertised in the official organ of the Minnesota State Medical Association and made an impassioned plea for joining the other thirty-three states which had co-operated with the AMA in the matter of advertisements. Dr. Buckley was a fine speaker and loved to match wits with others in forensic debate. His presentation of his viewpoint took the House of Delegates by storm and at the conclusion of his speech, his motion to establish a State Association-owned journal was carried. Dr. Robert Earl then presented the offer of the Editing and Publishing Committee of the *Saint Paul Medical Journal* to give the journal to the State Medical Association. Dr. Buckley moved that the matter be referred to a committee of five to make a report to the House of Delegates before its final adjournment. This motion was carried, and a committee consisting of Drs. J. W. Cochrane, Robert Earl, J. M. Armstrong, E. R. Hare and M. W. Smith was appointed. At a final meeting of the House of Delegates, this committee recommended the establishment of a new Association-owned journal with an Editing and Publishing Committee of five members, two to be appointed from the Hennepin County Medical Society, two from the Ramsey County Society and one from the state at large. Each Councilor District was to have one representative as an Associate Editor. The Editing and Publishing Committee was to have complete charge of the journal, select the editor, determine his compensation, et cetera., subject to the approval of the Council of the State Association.

The mere relation of the events leading up to the establishment of MINNESOTA MEDICINE fails to depict the travail which attended its birth. At the meeting of the House of Delegates in 1918, an attempt was made to rescind the action of the House the previous year which established MINNESOTA MEDICINE, on the grounds that Dr. Buckley's committee had ignored the instruction of the House in not submitting their findings to the county societies. Dr. Buckley took the floor, assumed the responsibility for failure in this point, signified his willingness to submit to the opinion of the House as to the importance of the omission, but added, "I have nothing in this world but my good name and have worked for it for thirty years, and when a man attacks my good name and charges me with being a political trickster I will follow him to the bowels of hell." MINNESOTA MEDICINE continued publication.

The first Editing and Publishing Committee of MINNESOTA MEDICINE consisted of Drs. Louis B. Wilson, Rochester; H. Longstreet Taylor and E. W. Buckley, Saint Paul, and John E. Hynes and Robert E. Farr of Minneapolis. The offer of the *Saint Paul Medical Journal* of its good will, advertising contracts and subscriptions was declined. Dr. E. T. F. Richards was selected as editor, with Ernest M. Hammes and Paul D. Berresford as Assistant Editors. Thus Minnesota became the twenty-ninth state to establish its own publication. Its purpose, as stated in the first editorial of the first issue which appeared in January, 1918, was to federate and bring into one compact organization the entire medical profession of the state of Minnesota; to extend medical knowledge and advance medical science; to elevate the standards of medical education. Lack of wholehearted support on the part of the members of the State Association has resulted in only partial attainment of the professed purpose of the journal.

Mr. J. R. Bruce of the Bruce Publishing Company, Saint Paul, was chosen as the publisher and business manager of the newly established journal. MINNESOTA MEDICINE, which was his first medical publication, was followed by numerous other medical publications in the ensuing years. Miss Irene Goette, librarian of the Ramsey County Medical Society, acted as secretary of the journal for several years until the work entailed in preparing the journal for publication was taken over by Miss Olive Seibert of the Bruce Publishing Company, who has given most efficient and co-operative editorial assistance through the years. Others in the employ of the Bruce Publishing Company sharing in the production of the journal a similar number of years are Mrs. Eva Appleby who, as secretary to the business manager, has handled advertising records and assisted in the journal make-up, and Mrs. Thomas H. Hall, who handles financial matters.

In March, 1919, shortly after my return from service in the Army, I received a letter from Dr. H. L. Taylor, president of the Editing and Publishing Committee, explaining that Dr. Richards had turned in his resignation as editor of MINNESOTA MEDICINE and requesting that I get out the April and succeeding issues of the journal until Dr. Bronson Crothers returned from Army service. I said I would; Dr. Crothers settled in Boston as a specialist in Nervous and Mental Diseases of Children and has not yet returned.

By April, 1953, exactly thirty-four years have elapsed since I got out the April, 1919, issue of MINNESOTA MEDICINE. During this period I have attended the meetings of State Medical Association secretaries and editors held almost yearly at AMA headquarters in Chicago and have received much inspiration from association with

(Continued on Page 383)

A CENTURY OF MEDICINE

1853-1953

S. MARX WHITE, M.D.
Minneapolis, Minnesota

MEDICINE as a discipline can be said truly to have begun with Hippocrates, but from the time of his death in about 355 B.C. physiologic concepts remained relatively static until the publication, in 1628, of *de Motu Cordis* by William Harvey. Harvey collected, in clear and definite form, ideas which had been stated but not confirmed by experiment.

Great names crowd the pages for the next century and a quarter. Our interest begins about 1853, the year of the founding of the Minnesota State Medical Association.

In any attempt to characterize in a journal article the progress of medical thought and practice of the past one hundred years, one must use the briefest of sketches. Hence, these vignettes will be etched about the border of the subject as indications only. The great mass, the central core, can be found only in the almost inconceivable amount of medical literature of the period from mid-century to mid-century.

Progress in medicine has been like that throughout nature and the history of man: revolutionary as well as evolutionary, with new starts in various directions, dependent on new concepts and new techniques. The physician of the nineteenth century is in process of becoming a scientist. He takes his place at the bedside of the patient. He follows the way nature has pointed out in the teaching of the biological sciences.

The nineteenth century brought a new aspect to the career of the physician. He becomes now no longer entirely dominated by systems.

Eminently experimental scientific positivist biological currents developed. The sorcerers and priests of ancient times, the astrologer or chemist of the fifteenth century, the bloodletter of the seventeenth, and the philosophizing academicians of the eighteenth have faded.

The eighteenth century had been characterized by the formation of theoretical systems. The middle of the nineteenth century found many of them still having violent advocates and corresponding opponents. In fact, remnants of some of them can be found extant today, and will persist so long as the mind of man retains its characteristic limitations. To name only a few: the animism of G. F. Stahl (1660-1734); the plethora of Hoffmann. One can still find Friedrick Hoffmann (1660-1742) Drops and Anodine which he introduced and sold at a handsome profit. One is often still importuned to use the "tonics" of his systems. John Brown (1735-1788) was the creator of Brunonism—the normal excitability of organs and the proper dosage of the stimuli thus constituting the state of health. In therapeutics sedatives were prescribed in the case of too much excitation (sthenic conditions) and stimuluation in depressed (asthenic) states.

François Joseph Victor Broussais (1772-1838) had served as an army surgeon in Napoleon's campaigns. He carried his rough schooling into his medical teaching. His therapeutics were sanguinary. Gastroenteritis was the basis of all pathology. A powerful antiphlogistic or weakening regime was adopted, the main features of which were to deprive the patient of his proper food and to apply leeches all over the body. Bloodletting became a sovereign remedy.

Franz Anton Mesmer (1734-1815) founded Mesmerism. Supporting the concept of the influences of the planets on physiological and pathological phenomena, he added to it a "magnetic therapy" derived from the ancient idea of curing by the laying on of hands. The American counterpart was the famous tractors of Elisha Perkins, a respected practitioner of Norwich, Connecticut—five guineas a pair.

Christian Friedrich Samuel Hahnemann (1758-1843) proclaimed the principle of "similia similibus curentur"—cure by drugs which produce a condition similar to the disease. Thus we have "homeopathy"—the treatment should be directed entirely against the symptoms, not against the disease. Another principle of the cult was that of potencies—successive dilutions of one in fifty, each such dilution increasing in potency until the thirtieth. The rise of homeopathy can be traced to the indiscriminate use of quinine and calomel

---

From the Nicollet Clinic, Minneapolis, Minnesota.
Dr. White is Professor of Medicine, University of Minnesota Medical School.

and in excessive dosage. It did no harm at a time when polypharmacy and shotgun prescriptions held sway in the ranks of regular medicine. Homeopathic physicians still had an enormous vogue as late as the beginning of the twentieth century.

P. C. A. Lewis (1787-1872) of France introduced the statistical method as a means for the scientific clinical investigation of disease. By it he was able to demolish Broussais' system.

In this period when experimental medicine was triumphantly asserting itself, but when ancient therapeutic ideas were still flourishing, we see the greatest contrasts in the history of therapy and pharmacology; on the one hand, the Viennese clinicians affirming that all treatment should be withheld in acute diseases, on the other, the disciples of Broussais who continued to practice bloodletting on a vast scale. New therapeutic fantasies, such as magnetism and homeopathy, existed along with the return to ancient methods, such as hydrotherapy, dietetics and other physiological methods. The pharmaceutical industry began to develop in Germany, England, France and the United States. Violent contests developed between those who in the treatment of febrile diseases advocated antipyretic remedies, the partisans of hydrotherapy, and those who tended toward therapeutic nihilism. Even as late as the turn of the century William Osler was reputed to be largely nihilistic in therapeutic practice. He once pointed out that there were scarcely more than a dozen and less than twenty really effective remedies in our armamentarium at that time.

Baths in various forms as therapeutic measures had survived throughout the ages. Spas and hot springs were in vogue. Dietetics was largely a matter of tradition and lacked the knowledge of body chemistry and metabolism of today. Physical therapy had its proponents but lacked the facilities and organization by which today it contributes so effectively to physical rehabilitation. Rest and exercise were known each to make a contribution toward restitution in certain fields.

Introduction of new drugs and discovery of active principles of many already in use were factors in making this an important period in pharmacology. Morphine, strychnine, quinine and atropine were in use and in 1859 Niemann first prepared cocaine. If one adds the crude preparations of mercury, iodides, iron, ipecac, alcohol, ether and chloroform the list is about complete. Pravaz described the first hypodermic syringe in 1853, thus opening up an entirely new field for the administration of drugs parenterally.

Justus von Liebig (1803-1873) had established the first laboratory of organic chemistry in connection with university teaching in 1826. He discovered hippuric acid and other uric acid compounds as well as chloral and chloroform. The most important step in establishing the new organic chemistry was the synthesis of urea by Wöhler in 1828. The scientific basis of nutrition was established by Max von Pettenkofer (1819-1901) and Karl Voit (1831-1908) who studied metabolism during activity and repose and measured oxygen consumption and heat production (calorimetry), using hermetically sealed chambers large enough to contain the animal under investigation and requiring long hours and days in the study.

Claude Bernard (1813-1878) was author of the aphorism that on entering the laboratory one should divest himself of the imagination as one does an overcoat. He was equipped with great experimental ability and constructive imagination, both greatly needed in the advance of science. He was a pioneer in endocrinology, establishing by 1857 the glycogenic function of the liver and laying the foundation for its metabolic relation to diabetes.

Ludwig von Helmholtz (1821-1894) invented the ophthalmoscope in 1851.

The most important and representative figure of the mid-nineteenth century is no doubt Louis Pasteur (1822-1895). He began as a chemist, studied fermentation by bacterial action and went on to disprove the theory of spontaneous generation which was until then a source of bitter discussion and error. His many discoveries were fundamental in medicine including the famous treatment of rabies, but the medical historian Garrison emphasized "the principle that pathogenic properties of a virus can be attenuated or heightened by successive passage through the bodies of appropriate animals led to one of the most luminous thoughts in the history of science—that the origin or extinction of infectious disease in the past may be simply due to the strengthening or weakening of a virus by external conditions."

Rudolph Ludwig Karl Virchow (1821-1902) taught pathology at Berlin until 1849 when he was forced to leave on account of his political beliefs. After seven years at Würzburg as professor of pathology he returned to Berlin having laid the basis of his epoch-making work on cellular pathology, replacing the ancient structure of humoral pathology which had dominated medicine for more than 2000 years. In 1847 he founded the journal which was to be the most famous for half a century, the *Archiv für Pathologische Anatomie und Physiologie und für Klinische Medicin.*

Robert Koch (1843-1900) discovered the tubercle bacillus in 1882. In consequence we have in our hands the means by which the "white plague" as pulmonary tuberculosis was once known—the captain of the men of death in the statistics of scarcely more than a generation ago—is being conquered. The bovine type causing the lymphatic form known as scrofula has already disappeared in those areas in our country and in the world where tuberculosis in cattle has been eliminated or where pasteurization of all milk for human consumption is compulsory.

Illustrative of the change in spirit and tempo of treatment over the centuries is the epic of "the countess powder" (pulvis comitesse). In 1638, the wife of the viceroy of Peru, the Countess of Cinchon, lay ill with an intermittent fever in the palace at Lima. A friend of her husband had learned of the virtue in fever of the bark of a certain tree and had sent a parcel of it to him. Administered by her physician, a rapid cure was effected. The tree itself was not described until exactly 100 years after the first use by the Countess, and the famous botanist Linnaeus established the genus "Cinchona" in her honor.

The plasmodium of malarial fever was discovered in 1880 by Alphonse Laveran. From then on, the application of the growing knowledge of the causative organism, the mode of transmission and methods of destruction of the organism and the vectors contributed to the world-wide conquest of the disease.

The first organized attempt to cross the Isthmus of Panama when American engineers built a railroad in 1849 to 1855 is said to have cost a life for every railroad tie, due to tropical disease. Ferdinand DeLesseps' attempt to build a canal ended in failure. Begun in 1881, it is reported that in September, 1885, the mortality reached the appalling figure of 176.97 per thousand laborers.

Col. William C. Gorgas (1854-1920) conquered yellow fever and malaria and the other tropical diseases of the Canal Zone beginning in 1904. Out of every 1,000 employes in 1906, 821 were hospitalized for malaria and in 1917—fourteen. The death rate from malarial fever per. 1000 population sank from 8.49 in 1906 to 0.11 in 1918.

Since medicine in its broad sense is the art or science of restoring or preserving health, a glance at the average length of life from ancient to modern times will be illuminating. All figures prior to the establishment of governmental birth and death records, of course, are only estimates. However, from the characteristics of fossil remains of the early iron and bronze ages the average is placed at about eighteen years, representing an infant mortality which we can scarcely conceive. As estimated from mummies, the figure was around twenty-two years 2,000 years ago. The next available records are derived from inheritance of property in England in the middle ages and indicate about thirty-five years. The figures do not change essentially up to the beginning of the nineteenth century. At the beginning of the period of our study (about 1852 in England and Wales), the figure is 40.9 and at the mid period about 1900-1902 in the United States is 49.2. Comparable figures for 1945 give 65.8 and for 1951, 68.42. Thus we see that the 27.52 years of life added during this past century of scientific advance is more than all the years previously since the dawn of man. The curve rises now each year. Let us not deceive ourselves: all this advance is not due to technical medical science and art. General standards of living, adequate food supply and shelter, all play a significant part. The most significant contribution, however, is in the unprecedented diminution in maternal and infant mortality and in the suppression of the infectious diseases.

Striking evidence of the advances of medicine—in its broad sense the art or science of restoring or preserving health—is found in a comparative study of mortality from disease and from casualty in war.

Throughout history, disease and epidemics have caused far greater losses in armies than have the casualties. They have often been the determining factor in defeat. World War I, ending in 1918, saw a reversal in this picture, and World War II, together with the present Korean conflict, has seen a saving of life hitherto believed impossible.

Blood transfusions and serum intravenously, together with antibiotics, perform seeming miracles. The Red Cross blood bank transmits these needed elements by airplane from the civilian pool to the theater of conflict in a matter of hours.

To recite within the narrow limits of this article the unprecedented advances of the last century and more particularly of the last fifty years is impossible. Many dates and many great names come to mind. One can sketch in only some of the most significant. No account of medicine in the western hemisphere would omit mention of William Osler (1849-1919). He was a man of wide culture, a wise clinician and was tireless in his pursuit and expositions of medicine. He became professor of clinical medicine at the University of Pennsylvania in 1885 and the first professor of medicine at the newly founded Johns Hopkins Medical School, Baltimore, in 1889. There he introduced a true bedside method of instruction in the wards where the students spent most of their time and acted as "clinical clerks." His textbook, published first in 1892, went through many editions and was the standard guide in the practice of Internal Medicine for a generation in the United States. In 1904 he became Regius Professor at Oxford. He died in 1919.

If an attempt is made to give separate consideration to diagnosis, treatment and prognosis, again confusion enters. Surgery and medicine have become inextricably mingled in that surgery is now no longer simply the removal of an offending part. Physiologic and pathologic processes are modified. The acid-producing portion of the stomach is being removed to modify digestion in duodenal ulcer. The circulation is being reconstituted in many cardiovascular conditions. Endocrine hormonal balances are being changed both by subtraction of all or part of an organ of internal secretion or by implantation of secreting tissue or injection of the hormone or its synthetic analogue.

Endoscopic technique has been developed to the point where the interior of nearly all hollow viscera and somatic cavities can be visualized. Early diagnosis is thus possible in the air passages and pleurae, the pharynx, esophagus and stomach, the anus and rectum to the sigmoid flexure of the colon, the peritoneum and the lower urinary tract. Material removed for biopsy gives opportunity for immediate microscopic assay. Positive diagnosis in many regions is furthered by the various biopsy procedures including the removal of tissue by punch. The Papanicolaou technique carried out by specially trained observers is growing in value in diagnosis of carcinoma of cervix uteri, bronchi, stomach and urinary bladder.

The roentgen ray reveals outlines of structures and cavities with remarkable accuracy. In conjunction with contrast media such as air or radio-opaque substances great diagnostic accuracy has developed and is advancing apace. The gastro-intestinal tract is compelled to reveal changes in its lumen from the oro-pharynx to the rectum. All ramifications of the bronchial tree can be studied.

The gall-bladder dye test reveals physiologic activity, malfunction and the presence—yes, even the absence—of calculi with an accuracy of approximately 96 per cent.

Kidney pelves and ureters can be outlined by means of radio-opaque substances introduced either through the blood stream or in retrograde fashion through ureteral catheters. Calculi, tumors, cysts and changes due to infection such as tuberculosis, pyelitis and ureteritis can be localized. Downward and lateral dislocation of the kidney shadow gives evidence of tumor lying above it as in the adrenal gland.

Localization of lesions in the brain and spinal cord has been greatly advanced by x-ray and electrographic methods. Pneumo-encephalography and encephalo-angiography reveal changes in the x-ray patterns within the skull. By the latter technique also the existence of intracranial aneurysms can be shown and in certain cases ligation of the internal carotid artery on the same side robs the lesion of its dangers. In a few cases local attack on the lesion is feasible.

Electro-encephalography provides a localizing mechanism in the diagnosis of cortical lesions.

Study of adrenal function can be made with accuracy. Substitution therapy with extracts and synthetic analogues can be made to sustain life. The recent production of cortisone gives us a therapeutic arm useful not only in this field but also in rheumatoid arthritis, the carditis of acute rheumatic fever and in many other fields. The influence of cortisone and ACTH on certain types of connective tissue disorder provides an instrument for the study and treatment of what has been roughly designated as the "collagen diseases."

The adreno-cortico-tropic hormone (ACTH) can be used to stimulate the adrenal cortex to put out added amounts of a substance very similar in its action if not actually "cortisone" itself.

Physiological and physical chemistry have developed to a point where the structure of the molecule is no longer secret. Manipulation of the constituent elements permits permutations and combinations almost to infinity. Synthesis permits production of substances of purity greater than can be secured by extraction.

By introducing radio-active elements into substances which are then introduced into the body, the course and sites of deposition can be followed by the Geiger counter and other methods of determining radio-activity. Probably the most striking example in this field is found in the use of radio-active iodine in hyperthyroidism. Given by mouth it is picked up almost in its entirety by the hyperactive thyroid tissue. The "half life" of this isotope is of a few days only. During this short period great numbers of the overactively secreting cells can be destroyed. After a few days the excess radio-activity has disappeared.

X-ray therapy cures many superficial lesions even of malignant character and modifies many physiologic processes. By radium and radio-active implantation many lesions can be reached where the x-ray is inadequate.

The isolation of insulin in 1921 by Banting and Best was followed by purification and modification until the diabetic need no longer suffer the consequences of the disease. Here the art of medicine is exemplified. An effective substitute for an insulin lack is available. The art lies in persuading the patient to pursue uninterruptedly a painstaking and meticulous regime when he has no symptoms to guide him.

Another form of substitution therapy is seen in what was once called pernicious anemia. After Minot and Murphy, about 1925, found the therapeutic value of liver, refinement methods produced an extract which made continuous substitution therapy possible. Again the art of persuasion comes into play.

Our already advanced and still advancing knowledge of hormones and vitamins places in our hands therapeutic aids of great effectiveness.

Our knowledge of the sensitizations and allergies—though still very limited—gives us aid in the successful treatment of some conditions once thought to be purely nervous in origin.

Knowledge in immunology and immunizations have brought about a radical reduction in the incidence and mortality of infectious diseases. The cultivation, identification and immunology of viruses continue to be difficult, but elaborate culture techniques are overcoming our limitations.

Refinements in the preparation of digitalis glucosides have given greater accuracy and safety in the use of these remarkably useful remedies.

The laevo-rotary isomer of quinine, quinidine, gives us control of many cardiac irregularities. Other remedies controlling cardiac irregularities and tachycardia are being discovered.

The anticoagulants have a wide area of usefulness. They have assisted measurably in prevention of intracardiac thrombosis and consequent embolism in cases of myocardial infarction. They are also useful in the prevention and treatment of intravenous thrombosis such as may occur in the deep veins of the legs and less commonly in the pelvic veins. In the recumbency and lessened activity incident to heart failure, the postoperative and postpartum states, old age, anemia and similar conditions, their early and skillfully controlled use prevents much morbidity and even death from pulmonary embolism.

The sulfanilamides and antibiotics are doing in purely medicinal fields something parallel to what antisepsis (and asepsis) did for surgery, although the manner of application and the degree of effectiveness may differ. They are changing the pattern of infections by their bacteriolytic and bacteriostatic actions. Because of the wide spectrum of action of certain of the antibiotics it is becoming in many instances less necessary to identify the invading organisms. Much time and expense can therefore be avoided.

Infant mortality between 1915 and 1948 inclusive fell in the U. S. registration area from 100.2 to 31.12 per 1,000 live births. In Minnesota the fall in the same period was from 70 to 28.33. In Minnesota alone, from 1915 to 1949 inclusive, infant and neo-natal deaths combined fell from 68.8 to 31 per 1,000 live births.

Involutional melancholia introduces a hazard into the period known as "Middle Age." For the unfortunate victim, there is a morbidity period of five to seven years from which recovery usually occurs spontaneously but during which he is a burden to himself, his family and his environment. Suicide also may cost his life, or his reputation or usefulness may be irrevocably impaired. Electro-encephaloplexy, known as "electro-shock therapy" (E.S.T.), under strict control has given an extremely high recovery rate within a period of a few weeks, thus robbing middle age of one of its greatest terrors.

The neo-modern surgery of the chest, lungs, heart and great vessels would be impossible without the newer methods of anesthesia using the physiologic effects of many drugs to control respiration, cardiac action and muscular relaxation.

Hitherto the disorders of the heart and great vessels have been susceptible only to hygienic and medicinal measures. At this point it is necessary to emphasize again the crucial part played by animal experiment in the development of the surgical techniques involved. Without the opportunity to develop dexterity and speed in operating and to learn the efficacy of techniques, no surgeon would dare invade the sacred precincts of the chest in man. Anomalous development is being corrected or compensated for, at least in part. Intrapulmonary arteriovenous aneurysms are being corrected by removal of the portion of the lung bearing the lesion.

In the past, many children who survived the neo-natal period with a malformed and malfunctioning heart and great vessels were doomed to invalidism or to death at about the age of puberty. What is now being done in rebuilding and reconstituting the circulation by surgery would have been impossible, nay unbelievable, twenty years ago. The stenosis of the pulmonary valve frequently seen alone or in combination with other congenital anomalies can be in good part corrected. Coarctation of the aorta is susceptible to surgical correction and is being recognized and corrected in early life. The surgical closure of a patent ductus arteriosus was one of the earliest triumphs in this field and provides a complete cure. The stenosed mitral valve of chronic rheumatic valvular disease is being widened by commissurotomy and other means.

The writer recently saw the photograph of a smiling, happy and healthy looking little girl of five and a half years, in whom closure of a large and incapacitating interatrial septal defect was performed by exquisitely trained surgeons. On September 2, 1952 at the Hospital of the University of Minnesota she had been anesthetized, her body temperature reduced in two hours to 26° C. This is 11° Centigrade below the normal average afternoon temperature of 37° C. or 19.8° Fahrenheit below the normal 98.6° F.

The surgical procedures took one hour and the warming after the closure took forty-five minutes. The actual suspension of cerebral circulation necessitated by the opening of the atria and suturing of the defect was not over seven minutes. By means of induced hypothermia, the oxygen requirements of the brain were thus reduced so that the function of brain cells could survive after suspension of circulation for six to seven minutes, double the survival time at normal temperatures.

This doubling of the time is adequate to allow swift delicate and dexterous intracardiac repair while cerebral circulation is suspended.

A dramatic procedure is that of opening the chest and massaging the heart into renewed activity when it has stopped beating under anesthesia.

Dorso-lumbar sympathectomy modifies in many instances the course of essential hypertension.

A striking illustration of the inextricable mingling of medicine and surgery is found in the way each complements the other in the newly developing treatment of pulmonary tuberculosis. It has been undergoing evolutionary change since the introduction of Forlanini's method of artificial pneumothorax in 1895. It was later attempted to rest the lung and close cavities by thoracoplasty and in suitable cases by phrenicectomy. Definitive treatment by removal of the diseased and cavitated areas has had to await the development of modern methods of anesthesia and the combination of surgery with the use of bacteriostatic and bacteriolytic substances but is now being accomplished.

Treatment for a period of several months by streptomycin and PAS prepares the patient. A carefully planned pneumectomy, lobectomy or segmental removal can be performed. Thus the cavitated areas which had been seeding infectious material into the environment are removed and the patient is freed from the incapacitating lesion. It is heartening to see these patients rehabilitated and seemingly cured. Many are already occupying fulltime jobs. It will take more time to learn how definitive the cure since the procedure is new. In Hennepin County's Glen Lake Sanatorium only eight such operations had been done from the time the institution was opened in 1916 to the end of 1949. Fourteen were done in 1950, 133 in 1951 and 167 in 1952. The operative mortality in this last year was 2.4 per cent. We have in our hands today the knowledge by which tuberculosis in man can be eradicated. The art consists in its application. A systematic program involving early detection in all elements of the population is imperative. Adequate treatment must be followed by rehabilitation and continuous medical supervision. Research must be pursued to add effectiveness. Professional and lay education is needed to insure support for the program.

The fundamental principle in civilization and culture is that knowledge of one shall become the property of all. To the glory of our profession this principle has been enforced throughout the history of medicine. It underlies our medical organizations as in the component societies beginning with the county and district societies up through the state associations and finally the national, the American Medical Association founded in 1847.

Following a report on medical education in 1910 by Abraham Flexner, there has been a great improvement in medical schools. Previous to that time, there were many second and third-rate schools, private and commercial in character. The total number, including good as well as objectionable, was 148 in the United States and seven in Canada—155 in all. This has been reduced to seventy-two four-year schools with high standards. The State governments make a great contribution to this number, furnishing thirty-one of the total. Minnesota has one of the earliest and best.

Before the first World War, our opportunities for graduate education were infrequent. Now anyone desiring training beyond the intern period has no difficulty in securing it in any grade or specialty desired.

Research facilities and institutes have multiplied. The Rockefeller Institute and Hospital have exercised an influence beyond their own size and means. Research has become an integral part of the function of all medical schools whose faculties in both fundamental and clinical branches have wholetime men.

Government agencies are now taking a significant part in the research effort. The National Institute of Health of the United States Public Health Service has a group for the study of such problems as cancer, heart disease and arthritis, to mention the most important at the moment. While purposes of the National Research Council extend into all fields of the national welfare, Medicine has had a share in its support through research grants.

In recent years many leading pharmaceutical houses have not only research projects of their own but have wisely contributed to research in Universities and wherever research facilities are available. Parenthetically, one could wish they could be led to realize how much greater the benefits from this than from the inordinate amounts of money spent in flash advertising which finds its way into the wastebasket.

The modern hospital plays a large part in preserving life and in proving the value of Medicine. In it science and art unite through organization in the pooling of knowledge for the protection of the individual. Hospitals exist in almost every community. Many small towns have institutions with excellent equipment. Here they tend to be private and philanthropic. All larger municipalities maintain hospitals. Warbasse has said: "To the glory of Medicine it may be said that the quality of the institutions has not only steadily but rapidly improved." In many, use of their facilities by Medical Schools provides a strong progressive staff and research is encouraged.

To those who knew the Veterans Administration in previous years, it is gratifying to see the revolutionary improvement in that service where now research is encouraged, with the result that the care of the veteran has improved immeasurably. Reorganized under General Omar Bradley with the aid of the Committee of Deans of Medical Schools, wherever a Veterans Hospital is or can be located near enough to a medical school, staff appointments are made by the deans and research and graduate teaching are fostered. By this means, men of top quality are secured. The task ahead is to prevent deterioration because of political control.

History repeats itself in the shift of preeminence in medical education from one country to another. Italy, France, England and Germany each has had a day of leadership. That the devastation of war in Europe has hastened the shift to the North American continent seems certain. We can only pray that the arts of peace in our country will supersede those of war and that our culture will not be overwhelmed.

ONE HUNDRED YEARS OF SURGICAL PROGRESS

DONALD C. BALFOUR, M.D.
Rochester, Minnesota

THE ONE HUNDREDTH annual session of the Minnesota State Medical Association is an appropriate occasion for recording the advances in medicine which have taken place in this first century of the Association. I appreciate the invitation to review the progress of surgery during this period, for it is clear that surgery has made a notable contribution to the most conspicuous era in the history of medicine. That is, in the last one hundred years surgery has advanced more than in all preceding centuries.

The Heritage of the Past

Modern surgery is based primarily on the major revelations of Vesalius in anatomy in 1550, of the circulation of the blood by Harvey in 1628, of the work of John and William Hunter in the Eighteenth Century pertaining to inflammation, the anatomy and physiology of the lymphatic system, the healing of wounds, and the ligation of blood vessels in their continuity, of antisepsis and asepsis by Lister through his application of the discoveries of Pasteur, and of anesthesia as applied by Morton and Long.

While John Hunter found surgery a mechanical art and left it an experimental science, the doors of the new world in medicine were opened with the advent of anesthesia, antisepsis and asepsis; but the progress of surgery in the past century has depended on the progress medicine as a whole made during this period. The development of the modern hospital with the evolution of surgical departments, medical education at undergraduate, graduate and postgraduate levels, training schools for nurses, the growth of medical libraries, and the extraordinary advances of visual education and of teaching museums, all have contributed to safe and sound surgical practice. Basically, the phenomenal growth of the art and science of surgery has been made possible through intercommunication, for, as Newman has pointed out, "the progress of civilization has been primarily dependent on intercommunication, and that in the modern as well as in the ancient world this is the first element of progress and the first contributor to the saving of human life and the postponement of death, and the man who extends its scope and builds its way is contributing much to make straight the highway of health." American surgeons, recognizing this, cultivated the practice of visiting surgeons and clinics at home and abroad, always with an open mind, with freedom from national prejudice and with the ability to apply what they saw, and in this way contributed enormously to the development of surgery in America in the forepart of this century.

Contributions From the Basic Sciences

The evolution of surgery to a science as well as to an art has come through correlation of surgery with the fundamental sciences, and groundwork for this reciprocal relation lay in the anatomic schools of continental Europe during the Seventeenth and Eighteenth Centuries. Cushing, in speaking on "Fashions in Surgery" set an approximate date of 1903 "when surgeons not only in this country but in other parts of the world had begun to show an awakening of interest in pathological physiology. . . . Though isolated individuals like Hunter had done so long before, surgeons as a class for the first time had begun to think in terms of function rather than of morphology. . . . Each generation has its investigative fashions which run more or less in the grooves of least resistance or greater promise."

The development of roentgenology during the last century has had a major role in the advances in surgery, for there is scarcely a disease or a pathologic condition in which the roentgenologist cannot contribute valuable and essential information, and it is in interpretation by the experienced roentgenologist that roentgenology has become of inestimable value to the surgeon.

Modern instrument-making likewise has contributed to surgical progress and enormously advanced the major objective of early diagnosis, and has made possible extraction of foreign bodies and excision of tumors which otherwise could not have been removed.

Reduction of Mortality Rates

The evolution of the art of surgery is evidenced

Dr. Balfour is an Emeritus Member of the Division of Surgery, Mayo Clinic, Rochester, Minnesota.

by one of the greatest achievements of the present surgical era; namely, the reduced mortality rate of operations. In the early part of the century, surgery was chiefly concerned with advanced lesions, large tumors and desperate emergencies, and it was in such conditions that pioneer surgeons acquired an enormous experience, for these operations often were of great magnitude and were carried out with what we now consider inadequate facilities. And, since they were limited largely to observation in their evaluation of surgical conditions, they acquired conspicuous clinical acumen and judgment and related this basic experience to the new problems arising from the rapidly expanding scope of surgery. Today, the surgeon has available innumerable aids in basic surgical research, in diagnosis, in interpretation of findings, in surgical technique, in preoperative and postoperative care, and in evaluation of results; but, in the application of these we must not forget the extraordinary competence of those pioneer surgeons who established sound general principles and who paved the way for the achievements of present-day surgery, which has brought such great prestige to American surgery.

"Living Pathology"

The development of modern surgery has made possible, as nothing else could do, the acquisition of knowledge as to the characteristics of diseases during life. Moynihan dramatized this fact by the term "living pathology," and he referred particularly to "the enormous increase in the number of abdominal operations in the early part of this century . . . with the result that we have been enabled to construct a pathology of the living as contrasted with the pathology of the dead." This revelation of the development of lesions and their complications influenced the trend toward earlier operation in those surgical diseases which in their ordinary course are progressive, and this has resulted directly in the saving of countless lives, and surgery in this respect gave a new concept of the course of chronic disease.

Anesthesia

The extraordinary changes which have taken place in all fields of surgery in the last one hundred years have been primarily related to advances in anesthesia, which continues to make conspicuous progress through departments of anesthesiology in teaching hospitals and in providing facilities for intensive investigations of properties of new anesthetic agents, of new preparations for supportive therapy and of new methods of administration.

Similarly, modern chemotherapy has written a chapter in the history of medicine which represents benefits to mankind comparable to those conferred by Lister and Pasteur. The pioneer work of the Oxford group (Florey and his associates) in establishing the bactericidal properties and the therapeutic indications for use of the antibiotics in the prevention and treatment of surgical infections initiated a notable era in the history of surgery. The extraordinary effects of these chemotherapeutic agents have naturally led to their abuse, and their routine use will not compensate for careless technique or disregard of sound surgical principles. As Sir Alexander Fleming, to whom mankind owes an eternal debt of gratitude for the discovery of penicillin, has well said, "antibiotics simply attack the bacteria; the surgeon must treat the patient."

Special Fields of Surgery

The most salient examples of the development of new fields of surgery are in neurosurgery and thoracic surgery. More than thirty years ago, Cushing made the prediction that the neurosurgeon of his day "would have reason for amazement could he foresee the novel procedures which those of the next generation would unquestionably come to develop, for they were only at the beginning." The accuracy of this prediction is seen in the localization and removal of neoplasms of the spinal cord, the treatment of injuries to the head and of lesions of the peripheral nerves, the surgery of the sympathetic nervous system, protruded intervertebral disks and lobotomy for mental disorders. In surgery of the sympathetic nervous system, for example, if one considers the chronic diseases which in their development may be dependent on primary spasticity of arterial supply, it is not too venturesome to predict that by means of operations on the sympathetic nervous system some of the most disabling and serious diseases of modern life may be controlled.

As in neurosurgery, surgery of the thorax is an achievement of this modern era. The advances in our knowledge of the physiology of respiration and circulation, to which research in aviation gave such impetus, have contributed greatly to the safety with which operations on the lung, heart and great blood vessels can be carried out.

Disclosure by surgery of the fact that cancer of the lung is one of the more common malignant lesions, the surgical treatment of pulmonary tuberculosis by excision of the lesions, and the surgery of the great blood vessels and of congenital and acquired cardiac anomalies, mark one of the great epochs in the history of surgery.

In the earlier years of surgery of the thyroid gland, operations were confined to thyroid tumors, adenomatous and colloidal, and to those which were not associated with disturbances of metabolism. The gradual recognition and proof that certain types of diseases of the thyroid gland are responsible for profound toxic disturbances, due to perverted thyroid secretion, and the control of this by iodine, have been one of the triumphs of modern medicine, and operations for toxic adenoma and for exophthalmic goiter followed establishment of these facts.

The surgical management of diseases of the eyes, ears, nose and throat has been radically changed with the introduction of chemotherapy in the treatment of inflammatory conditions. But one of the most dramatic achievements in this field has been the fenestration operation for deafness.

Surgery of the genitourinary system has been almost entirely developed within the century. The outstanding achievements have been in the earlier surgical management of prostatic hypertrophy. In this, American surgeons have pioneered in the development of perineal prostatectomy and transurethral prostatectomy. The latter method was made possible by the introduction of new instruments of precision which in turn made possible satisfactory relief of prostatic obstruction with less disability. In surgery of the kidney and ureter, plastic operations dealing with various types of hydronephrosis have been real advances, and the success with which exstrophy of the bladder can be dealt with by cystectomy and ureteral transplantation has been a genuine surgical triumph.

The wars of this century have given impetus to all fields of surgery, particularly orthopedic surgery, plastic surgery and surgery of the blood vessels, and in the amazing expansion of the field of physical medicine.

The progress of surgery during the past century always will be identified with the advances in abdominal surgery. This has been largely due to two factors, (1) the number and variety of diseases of the abdomen, and (2) the principles of asepsis making possible safe opening of the abdomen. Earlier procedures were undertaken for the relief of serious complications, rather than for the disease itself, and the development of abdominal surgery has clarified, as nothing else could, the nature of these diseases, their course and complications, and has established the rational basis for treatment. Experience in surgery of the gallbladder and ducts has established the principle that removal of the gallbladder gives more permanent results than drainage, and the development of elaborate procedures for reconstruction of the bile ducts is a notable accomplishment. The value of education of the public and the profession in the importance of early recognition of acute disease, for example, appendicitis, is reflected in the negligible mortality rate of this disease today. The results of splenectomy for various disorders of the blood has greatly stimulated the field of hematology, since changes in the blood picture are pathognomonic in many of the diseases associated with splenomegaly.

Special Surgical Conditions

A distinct achievement in this century has been the demonstration that diaphragmatic hernia is a relatively common condition, that it is associated with a definite clinical syndrome, that the condition can be detected by a special roentgenologic examination, and that the hernia can be successfully repaired by surgery. Surgery of the esophagus for both benign and malignant lesions has made extraordinary progress in recent years, although esophageal stricture, cardiospasm and bleeding varices still present unsolved problems. The possibilities of controlling portal hypertension by various surgical procedures are still to be evaluated, but already fundamental achievements have been made. Surgery has contributed much-needed knowledge about diseases of the pancreas, and the fact that total pancreatectomy can be done with maintenance of good health opens inviting possibilities for the future.

The development of surgery of the gastrointestinal tract is a story of persistence in the face of seemingly insurmountable odds, of technical ingenuity and physiologic research, from the crudeness of the first gastrotomy as performed by Oriental surgeons to the finesse of total gastrectomy as it is accomplished today. Surgical treatment of diseases of the large bowel, particularly carcinoma, has become so highly developed that most extensive procedures, such as removal of the entire colon, are now possible with lower rates of mortality than ever before, and with a higher percentage of permanent cures in cases of carcinoma than can be attained in the treatment of carcinoma of any other part of the intestinal tract.

Diseases of the stomach and duodenum are exceedingly common, the benign lesions alone in the aggregate being responsible for more ill health than disease of any other organ. Malignant disease of the stomach takes a heavier toll than does any other abdominal carcinoma. The chief difficulty at present in the treatment of the most common of benign lesions, namely, peptic ulcer, is inadequate knowledge as to the cause of the disease. In treatment of malignant lesions the handicap consists largely in the lack of opportunity to make an early diagnosis.

The surgery of peptic ulcer began with treatment of the complications of the disease, the most frequent indication for surgery being pyloric obstruction. It was found that such obstruction could be circumvented by gastroenterostomy, and the operation was so spectacularly successful in a high percentage of cases that it became the established procedure for duodenal ulcer, whether or not obstruction was present. Then disappointing results supervened. It soon became evident that in cases of early duodenal ulcer, particularly if the patients were young and gastric acidity was high, there was a special risk that ulcer would recur, usually in the jejunum, and in relation to the new stoma similar to that which a duodenal ulcer bears to the pylorus. Gastroenterostomy, however, continued to be employed for lesions of a type for which it had been shown by Mayo and Moynihan to be efficient. It is still indicated in carefully selected cases, for it has the advantage over all other surgical procedures for ulcer in that it is completely reversible.

Nevertheless, the disappointing results of gastroenterostomy in certain cases led to the introduction of various procedures designed to avoid use of the jejunum. The earliest of these were operations on the pyloric outlet, and they were based on the assumption that pylorospasm might be a factor not only in producing the ulcer but also in preventing its healing. By ablating the muscle and thus relieving the pylorospasm, it was thought that an ulcer which could not be removed would undergo healing and sufficiently reduce secretory activity to prevent recurrence of the lesion. After they had undergone various types of pyloroplasty, a considerable percentage of patients remained well, but the ineffectiveness of the operation in some cases was an indication for more radical procedures.

This trend in turn led to performance of partial gastrectomy, which became the operation of choice in chronic duodenal ulcer. Some sequelae of partial gastrectomy have been responsible for the employment of methods to avoid the use of the jejunum; for example, the Billroth I operation, vagotomy, pyloroplasty and various combinations of these. The recent attention which has been drawn to the usefulness of gastroenterostomy, particularly with vagotomy, is of significance. The safety with which extensive gastrointestinal operations can be carried out today is indicated in a recent report by Moroney of 100 cases in which a segment of the colon was substituted for a removed stomach. The great variety of procedures, either single or multiple, which have been suggested in the surgical treatment of peptic ulcer can be evaluated only after the passage of time. Treatment, whether medical or surgical, will continue to be empirical until the cause of the disease is known.

Comment

The future of surgery depends on recognition of the fact that superlative skill, judgment and surgical experience are the first requirements of a great surgeon. The science of surgery will rest on a still firmer foundation when its development is inspired and directed by those who are masters of the art of surgery. Whatever the future of surgery may hold, it is safe to say that the past century will be known as the surgical era. In this respect, the surgical profession of Minnesota may well take pride in the part it has had in these remarkable advances which are represented in the 100 years of the Minnesota State Medical Association. It has been the integration of sound clinical practice, a high level of undergraduate and graduate teaching, and productive clinical and experimental investigation which has brought the epoch-making contributions to the science of surgery through which the better care of the surgical patient has evolved. In all of this, the profession of Minnesota, the Medical School of the University, and the Mayo Foundation have had conspicuous parts. These foundation stones, added to those of past eras, have been well and truly laid, and it is upon these that the surgery of the future will be built.

EARLY ORTHOPEDIC SURGERY IN MINNESOTA

CARL C. CHATTERTON, M.D., F.A.C.S.
Saint Paul, Minnesota

FROM the time of Andry, the word "orthopedic" has been identified with the treatment of deformities, and an "orthopedist" has been one who treated deformity. But it was not until Stromeyer, in 1830, demonstrated the feasibility and value of subcutaneous tenotomy, that orthopedics obtained its first firm foothold in the profession. Both before and after Stromeyer's time, however, mechanico-therapy was the fundamental part of treatment of deformities. In an essay by Dr. H. J. Bigelow in 1844, in addition to clubfoot, curvature of the spine, and torticollis, he treated stammering and strabismus, and it seems clear at the date he wrote, that operative treatment was synonymous with subcutaneous tenotomy or myotomy, and that any condition requiring either of these operations was to be classified under orthopedic surgery.[4]

About 1852 an American surgeon, Dr. H. G. Davis, published an essay in which he advised the use of elastic traction by means of portable apparatus in the treatment of hip-joint disease. He also demonstrated the value of traction apparatus for overcoming the deformities occasioned by chronic articular lesions. The treatment of Potts' disease was demonstrated by Dr. Davis and Dr. C. F. Taylor. Dr. Lewis A. Sayre, along with Dr. Taylor, amplified Dr. Davis's apparatus for the treatment of chronic and progressive deformities, and under their leadership the treatment of chronic joint disease and spinal disease became a distinctive feature of the American School of Orthopedic Surgery.[13]

The most reliable way to be sure of those first interested in orthopedic surgery in Minnesota, requires a search of early articles written on various subjects that were especially orthopedic in nature, and a check of the faculties of the various institutions of medical instruction that appeared in Minnesota's infancy.

Previous to 1870, in a single room of the old stone house in the rear of St. Joseph's Hospital, a preparatory school was founded by Dr. Daniel Hand, Dr. Alex Stone, and the elder Dr. Stewart. Equipment: one pine table, a few kitchen chairs, some books, and a skeleton. Material: an occasional amputated limb handed out to them by the old hospital.[3]

In 1870, the Saint Paul School of Medical Instruction was formed by a number of Saint Paul physicians who believed greater facilities should be afforded students desiring to obtain a preparatory medical education than could be obtained from any single instructor. The object of their school was not to take the place of a regular college, but to prepare students for a better understanding of lectures they might hear in a college course. This enterprise was transferred to Minneapolis in 1878. It continued until 1885 when the faculty differed among themselves, and the Saint Paul portion withdrew and established the Saint Paul Medical College at 204 West Ninth Street.[2]

The Saint Paul Medical College claimed success because of the unusual amount of its available clinical material, and a building centrally located on the principal business street, near streetcars. The building commanding a fine view of the Mississippi, had a large comfortable lecture room, a chemical laboratory and clinical room, and a large, cool dissecting room. The lecture room was used by the Ramsey County Medical Society for monthly meetings, and to those deliberations the students were invited. The faculty was composed of: Alexander Stone, M.D., Dean and Professor of Obstetrics, Gynecology, and Medical Jurisprudence; Charles A. Wheaton, Professor of Anatomy and Clinical Surgery; Dr. F. Dedolph, Professor of Pathology and Dermatology; Dr. Talbot Jones, Registrar, Professor of Psychology and Diseases of Children; Dr. F. A. Dunsmoor, Professor of Surgery; Dr. Francis Atwood, Professor of Ophthalmology and Ototomy; Dr. James Davenport, Professor of Materia Medica and Therapeutics; Dr. Jay Owens, Professor of Theory of Practice of Medicine and Diseases of the Throat; Dr. Ernest F. Horst, Professor of Nervous Diseases and Orthopedic Surgery; and George F. Weitbrecht, Professor of Chemistry.

At a later date the St. Paul Medical College merged with the new Minnesota Medical College at Minneapolis. This college occupied a part of a magnificent building known as the old Winslow House, situated in East Minneapolis, having a capacity of three hundred rooms. This school was formally opened on October 31, 1881.

Dr. Horst was Professor of Orthopedic Surgery in this school also.

In 1883, a plan prepared by President Folwell and others at the University[12] was presented to and adopted by the Board of Regents, creating the College of Medicine and Surgery, not as a teaching body, but as an examining body. The Legislature passed the first State law requiring all physicians to register with the faculty of this college. In 1887, the Legislature took a hand in medical affairs in the creation of an Independent Board of Medical Examiners under the first law of its type in the United States known as the Examination Law. This law discarded the diploma as evidence of medical education, and required examination of every applicant for license to practice medicine in Minnesota. In February, 1888, at Dr. Millard's instance, representatives of the faculties of the Minnesota Hospital College and Saint Paul Medical College appeared before the Board of University Regents with the offer to surrender their charters and properties in the city for the temporary use of the State. This offer was accepted, and the College of Medicine and Surgery, Homeopathic Medicine and Surgery, Dentistry and Pharmacy was established at the University. Dr. James E. Moore was elected Professor of Orthopedic Surgery.

On April 6, 1875, the Minnesota Orthopedic Institute was founded. The object of the corporation was the manufacturing and vending of mechanical surgical apparatus, and the application of such apparatus to the deformities and deficiencies of the human body, wherever surgical, mechanical or electrical apparatus appliance or movement treatment is required. The first officers were Dr. J. H. Stewart, President; Dr. E. W. Hand, Chief Surgeon; Dr. C. E. Smith, Assistant Surgeon; Dr. R. W. Sweeney, Chief Surgical Mechanic. The office was at 7 West Third street.

Dr. Jacob H. Stewart was Surgeon to the First Minnesota Regiment in 1861. On May 30, 1928, the chancel window at the new Fort Snelling Memorial Chapel was dedicated to him as a Regimental Surgeon and an outstanding figure in Minnesota politics, State Senator, Representative in Congress, Postmaster of Saint Paul, Surveyor General of Minnesota, four times Mayor of Saint Paul, Ramsey County Physician, and was apparently interested in mechanical orthopedic apparatus.

Many interesting and instructive articles were published by these early pioneer physicians. The first I have been able to discover on orthopedic surgery were as follows:

1. *Orthopedic Surgery as Applied in the Use of the Tenotome,* by Dr. A. B. Stewart, Winona, Minnesota. Northwestern Medical and Surgical Journal, 1:349-359 (May) 1871.

The article is a clever dissertation of the use of the tenotome. Dr. A. B. Stewart began its use in 1864. Principal discussion of the paper is whether to cut from without inward, or whether from within outward. He mentions muscles which might be cut by a tenotome; nothing about sterilization of the tissue or knife, nor of cold compresses after operation. Many operations were done without anesthesia of any kind.

2. *Transactions of the Minnesota State Medical Society,* Wednesday, June 22, 1881. Dr. Horst read the report of the Committee on Orthopedics. This was its first report and was illustrated by presentation to the Society of a young man and a boy, both of whom were afflicted with spinal curvature and wore the paper jacket used by Dr. Ernest F. Horst, which was claimed to be superior in various respects to the plaster apparatus introduced by Dr. Sayre.

3. *Early Diagnosis in Hip Joint Diseases* by Dr. James E. Moore. Northwestern Lancet, 8:141-144 (June 1) 1888.

This is a very classical and interesting article, and outside of the x-ray findings and present-day laboratory technique, it is modern in its conception.

4. *Orthopaedic Surgery,* by Dr. James E. Moore. Northwestern Lancet, 9:231 (Sept. 1) 1889.

5. *Treatment of Hip Joint Diseases,* by Dr. James E. Moore. Northwestern Lancet, 9:311 (Dec. 1) 1889.

6. *Orthopaedic Surgery,* by Dr. Arthur J. Gillette. Chairman of the Section. Transactions of Minnesota State Medical Society, Page 66, 1890.

7. *Prognosis in Orthopaedic Surgery,* by Dr. J. E. Moore. Northwestern Lancet, 10:18-20 (Jan. 1) 1890.

8. *Rachitis and Resulting Deformities,* by Dr.

Arthur J. Gillette. Northwestern Lancet, 10:179 (June 1) 1890.

9. *Potts' Disease,* by Dr. Arthur J. Gillette. Transactions of the Minnesota State Medical Society, Pages 183-193, 1892.

10. *Orthopaedic Surgery.* A book published by Dr. James E. Moore in 1898.

There may have been other articles published during this time by men on orthopedic subjects, but those mentioned seem to be the early papers in Minnesota.

Dr. Ernest F. Horst was born at Fort Wayne, Indiana, in 1853. In May, 1859, he came with his parents to Saint Paul and obtained his elementary education in private and public schools of the city, after which he entered Concordia College at Fort Wayne, where he studied for two years, and then spent two years at Northwestern University. He commenced the study of medicine in Saint Paul, attending Saint Paul Preparatory Medical School. From there he went to Chicago in 1874 to attend lectures at Rush Medical College. In 1876, he was graduated from the University Medical College of New York City, and the same year was appointed Junior Assistant Physician and Surgeon to the Hospital for the Ruptured and Crippled in New York City. In 1879, he returned to Saint Paul to engage in practice. He died in Saint Paul on March 26, 1909.[1] He was a man of medium stature, modest, unassuming, and capable. He did some work at St. Joseph's Hospital. His office was at Third and Maria.[10]

Dr. James E. Moore, surgeon, was born in Clarkville, Pennsylvania, March 2, 1852. He died from pernicious anemia in Minneapolis on November 2, 1918. In 1871-72 he studied medicine at the University of Michigan at Ann Arbor and took a second course at Bellevue Hospital Medical College, New York, where he was graduated in 1873. He moved to Minneapolis in 1882. In 1886, he went to Europe and when in London studied at the Royal Orthopaedic Hospital. He took special instruction in surgery, and particularly in orthopedic surgery at the New York Orthopaedic Hospital. Upon returning to Minneapolis in 1888, he confined his work to surgery—the first in the Northwest to limit himself to that specialty. He was a member of the American Orthopaedic Association, Western Surgical Society, and Southern Surgical. He was chairman of the Surgical Section of the American Medical Association in 1903. As a teacher, he was classed as one of the four great teachers of surgery in the United States. He published a text on Orthopaedic Surgery in 1898, and wrote and published over 200 papers on surgical subjects. In his early years, he was devoted to orthopedic surgery, but later, as Professor of Surgery at the University of Minnesota, taught general surgery of the highest standard.

Arthur J. Gillette was born October 28, 1863 on a farm now occupied by the Swift plant in South Saint Paul. He died in Saint Paul on March 23, 1921. He attended a rural district school, later enrolling as a student in Hamline University in Saint Paul. At twenty, he entered Minnesota Hospital College where he studied from 1883 to 1885, when he transferred to the newly formed Saint Paul Medical College, and obtained a degree in 1886. Following his graduation, he went to New York, where he took a course in the newly recognized specialty of orthopedic surgery under Dr. Sayre. He served one year as a resident in the New York Orthopaedic Dispensary and Hospital. Upon returning to Saint Paul, he began the practice of general medicine, since orthopedic surgery as a specialty was an unheard of innovation in the West. After 1890, he limited himself to orthopedic surgery. After showing the need and accomplishments by teaching the profession through practice and propaganda, he was offered an instructorship at the University of Minnesota in 1895. In 1897, he was elected Clinical Professor and in 1898 Full Professor. In 1913, he was given charge of an Independent Department of Orthopaedic Surgery. His published papers covered almost all phases of orthopedic surgery, were of careful logic, clear, and concise. He was a charter member of the American Orthopaedic Association, and its president in 1901, and was President of the Minnesota State Medical Association in 1917. Essentially conservative, he was among the first to operate for fracture of the neck of the femur. Dr. Gillette's most important work was his effort in establishing the first state-supported orthopedic hospital and school in the United States. His first known effort to secure state aid for crippled children was a paper presented before the Board of Charities and Corrections of the state, at a meeting in Mankato. The next year he appeared before the Legislature, and due to his efforts a small appropriation was approved. First a ward, then a building was used at the City and County Hospital (Ancker Hospital) until the building of the present hospital at Phalen Park, Saint Paul, in 1911-12. At that time all the children were transferred to the institution that bears his name. When orthopedic surgery was still in its infancy, he brought Minnesota to the front rank. His vision and persistence were soon followed by other states establishing schools and hospitals for their crippled children and adults.

It is my best judgment that Dr. Ernest Fredrick Horst was the first trained orthopedic surgeon in Minnesota. Dr. J. E. Moore was the first real teacher of orthopedic surgery in the state. Dr. Arthur Gillette was the first to envision the care of the indigent cripple by the state, and through his efforts the first state-supported hospital (and school) was established.

It is impractical in an article, limited in space as this one is, to tell of the careers of the following orthopedic surgeons, now deceased, who have practiced in Minnesota: Charles Reed, Emil Geist, Alex Colvin, Albert Flagstad, Wm. Von der Weyer, Joseph Kutn, Mark Tibbits, Vernon Hart, Otto F. Schusler, Paul Geisler and N. K. Knauf. The same applies to the group of orthopedic surgeons who are now in active practice and have made valuable scientific contributions during the last half of the past century.

Acknowledgment

A great deal of information contained in this article was obtained from Dr. John M. Armstrong who completed the History of Medical Practice in Ramsey County up to 1900 (Minnesota Medicine, Vol. 21, 22) and also from Dr. Arthur Hamilton's History of Medical Practice in Hennepin County up to 1900 (Minnesota Medicine, Vol. 22, 23).

STATE BOARD OF MEDICAL EXAMINERS

(Continued from Page 343)

and four of these reinstated since 1928. Thirty-three have been suspended, with twenty-two reinstated.

The Minnesota Basic Science law has been tested in the Minnesota Supreme Court on several occasions and has always been upheld. The right of an individual to free choice of physician has been established in Minnesota Supreme Court in several instances. A suspension of license imposed by the Board was fought by one physician to the United States Supreme Court where the action of the Board was upheld. Another hard-fought case went to the United States Supreme Court, when a layman in Minneapolis was convicted of violation of the Federal Pure Food, Drug and Cosmetic law in the sale of a product called "Powder X." His conviction was upheld, and he paid a fine. A recent opinion of the Minnesota Supreme Court held that vitamins are drugs and not food and must therefore be sold in accordance with the pharmacy laws. This eliminates the sale of vitamins from grocery or any store other than a drug store.

The Board reports all court cases in Minnesota Medicine in order that the profession may be well informed.

An annual directory of all registered physicians is printed annually and has a wide distribution among law-enforcing agencies, medical societies, insurance and business companies, universities and libraries.

The Board is fortunate in having excellent medical laws that govern its procedures and support its actions.

PROGRESS IN PEDIATRICS IN MINNESOTA

1853-1953

O. W. ROWE, M.D.
Duluth, Minnesota

WHEN the Minnesota Medical Society was organized, the field of pediatrics as a branch of medical science had not developed. The members of the new society had no information on the development of children or on their physical and mental health from infancy through childhood and adolescence. The literature—historical and current—was scanty. Some very early observations suggest that a few medical conditions were recognized, but in primitive times little value was placed on infants' lives. The only concern seems to have been the elimination of the unfit and the unwanted.

Hippocrates recorded the first observations that could have been of help to the early practitioner in the care of children. He thought that impure water and improper nutrition might be the causes of certain diseases and that cures were brought about by natural processes and that treatment should be directed towards supporting these forces. Until the 18th Century, few contributions were of value in establishing a scientific basis for practice in this field. These offerings were often highly speculative and the treatment empiric. The busy medical practitioner had to depend on his own observations and experiences in the care of children which left him almost totally unprepared to meet the demand of what must have been a large part of his practice.

More than thirty years elapsed between the foundation of the medical society and the organization of a medical school at the University of Minnesota. Progress during this period was very slow. The general practitioner was not without some pediatric assistance, however. Jacobi, the father of American pediatrics, gave the first lecture on clinical pediatrics at the College of Physicians and Surgeons in New York in 1857. This example was followed slowly by the medical colleges, and divisions of Pediatrics were formed, usually attached to the Department of Medicine, but occasionally to the Department of Obstetrics and Gynecology. Medical graduates from New England and the middle states who had had the advantage of such innovations migrated to the larger cities in our state and to the large number of small towns scattered in our rural and mining areas. These men brought with them some measure of formal professional training which stimulated those with whom they had contacts.

That the practice of pediatrics progressed slowly through this period is indicated by the first paper on this subject published in Minnesota. In the second issue of the *Northwestern Medical and Surgical Journal,* published in 1872, there appeared an essay by Brewer Mattocks, M.D., of Saint Paul, entitled "Children: Their Diseases and Treatment." The conditions inducing him to write on this subject were: "Fully one half of the deaths that occur in the daily practice of the physician are of infants—children under five years of age. Fully two thirds of the patients we are called upon to visit are children." His plea was for a more sympathetic attitude on the part of his fellow practitioners. He evidently believed that sympathy would lead to a desire of knowledge and eventually to better care of their little patients. It is regretted that his efforts failed to produce the desired results.

Progress was also very slow during the next two decades. The few contributors confined themselves largely to the symptoms and treatment of disease. Few of these publications were available until after the organization of the Section of Pediatrics of the American Medical Association in 1880. The earlier meetings of the section were concerned with such clinical problems as diphtheria and membranous croup. These reports and the entire program of the first meeting of the American Pediatric Society in 1899 became available. At this meeting there was one paper on diarrhea of infants and another on the feeding of infants. The absence of knowledge of feeding even well infants with artificial foods forced many practitioners to become ardent propagandists for maternal nursing. The feeding of the sick child was too often influenced by the

---

From the Department of Pediatrics of The Duluth Clinic, Duluth, Minnesota.

teaching of Broussais and others who, following purging and occasional bleeding, ended with systematic starvation.

The first orderly attempt at artificial feeding of infants was introduced by Rotch of Harvard in 1896 and was elaborated and made available to the general practitioner by Holt in the first edition of "The Diseases of Children." This was an intricate mathematical exercise requiring more knowledge than was available. "Top milk" feedings were used almost exclusively and percentages of fats, carbohydrates, and proteins meticulously calculated for each formula. All of this was extremely complicated. A chart designed by Charles Hendee Smith to simplify the problem was one of the most complex figures distributed by *Archives of Pediatrics*. Often a mother, after her baby failed to gain when following the advice of her physician, was forced to use one of the "prepared foods" available in the drug store on which her baby would gain rapidly. These prepared foods were essentially high-carbohydrate, high-calorie foods and were sold in large quantities.

It was Haubner of Leipsig, later of Berlin, whose work first placed Pediatrics on a scientific basis. With Rubner, he investigated and devised a method of estimating the complete metabolism and energy quotients in various conditions of infancy. Haubner, in addition to being a distinguished teacher and organizer of scientific investigations in the field of medicine, established a school for training men to become leaders and teachers in pediatrics. One of these, Dr. Julius Parker Sedgwick, became the first full Professor of Pediatrics in the medical school in the University of Minnesota.

The medical school of the University of Minnesota was organized in 1888. The three private medical schools of the Twin Cities surrendered their charters and later the medical school of Hamline University joined the new organization. Under the department of medicine lecturers, Dr. Charles L. Wells is listed as giving some attention to the branch then spoken of as pedology. It was not until 1895 that Dr. James Trent Christison appeared as a clinical lecturer in pediatrics. Dr. Christison was an excellent teacher and a wise counsellor in this branch of medicine. It was at his request that the hours assigned to pediatric instruction were increased from 90 to 200 hours. He maintained his interest and enthusiasm for pediatrics until he retired some forty-five years later. His first title was Assistant Professor of Pediatrics under the Department of Medicine. His last was Assistant Professor of Pediatrics, Emeritus.

Dr. Walter Reeves Ramsey appeared on the scene two years after the advent of Dr. Christison. He was an excellent teacher. He exercised his influence through his wide acquaintance and position on many boards for the advancement of the department and in ironing out differences which were bound to occur in a growing institution. One of Dr. Ramsey's greatest contributions was the organization, building and equipping of the Saint Paul Children's Hospital. This was the first hospital in the state devoted exclusively to children. The hospital, in addition to its own intensive program, gives instructions to interns of other hospitals and has many other outside activities. Dr. Ramsey is now retired with the title of Assistant Professor of Pediatrics, Emeritus. At the beginning of the century, Doctors Christison and Ramsey gave practically all of the pediatric instruction at the University Medical School.

In 1905, Dr. Julius Parker Sedgwick came to Minneapolis to practice pediatrics. He was the first man in Minnesota to limit his practice exclusively to this branch of medicine. He taught pharmacology and physiological chemistry at the University and later became interested in the development of the pediatric department. On November 3, 1915, the minutes of the Board of Regents made the following statement:

> "Voted on the recommendation of the administrative board of the Medical School to recognize as departments, the present divisions of Pediatrics and Eye, Ear, Nose, and Throat, with the understanding that this action becomes effective November 1, 1915, and that the present heads of the divisions are designated as heads of the new department."

In the *Medical School Bulletin* for 1914-1915, Dr. Julius Parker Sedgwick's title is given as Associate Professor of Pediatrics and Chairman of the Division of Pediatrics. He was promoted to full professor and chairman early in 1915 and, in November, he was named department head. Dr. Sedgwick was well equipped to evaluate and utilize to its fullest extent the enormous amount of original work done in the clinics and laboratories, both here and abroad. He was a man of wide vision and great organization ability. He and his associates, in the brief period of eight years, established a department that ranked as one of the foremost in the nation in research and teaching. With the assistance of Professor Jennings C. Litzenberg of the Department of Obstetrics, he organized the Newborn Clinic—the first of its kind in America. Many of the investigations of this department were of immediate value to the practicing physician. One of these was the study of the comparative value of artificial feedings and maternal nursings. He succeeded in getting a large proportion of the mothers to nurse their babies. The precipitous drop in infant mortality in areas where breast nursing was established indicated a relationship between maternal nursing and the lowered mortality rate. He believed that most mothers, if encouraged and properly instructed, could nurse their babies. Dr. E. J. Huenekens, some years after this program was in effect, showed that 93 per cent of the mothers in Minneapolis could nurse their babies for three months and nearly 80 per cent to the ninth month. Professor Sedgwick's research was not limited to the newborn. He and his outstanding associates investigated many fields in Pediatrics. He edited Freers's two books on Pediatrics. In addition to the work in this department, he enjoyed a large private practice until he became a full professor and head of the Department of Pediatrics. In his private practice, he attracted a group of exceptional men, most of them trained in the European centers. These men also served in various capacities at the University. Among these was Dr. Frederick Rodda, who, after Dr. Sedgwick's death in 1923, organized the Children's Clinic in Minneapolis. Both of these clinics were large factors in the development of pediatrics in Minnesota.

After Dr. Sedgwick's death, Professor Clemens von Pirquet was elected as his successor. He remained only a short time and the vacancy was filled by Dr. Fred Schlutz, who served until 1930. He was succeeded by Dr. Irvine McQuarrie, who has been full professor and head of the department since. Under Professor McQuarrie, the Department of Pediatrics has progressed at a very rapid rate. He has affiliated the hospitals of Saint Paul and Minneapolis with the University Hospital and Children's Clinic, so he has an immense amount of clinical material for teaching purposes. While the primary function of the department is to teach, the reputation of his department will depend largely upon the research that he has stimulated and has carried through to successful conclusion. One of his larger contributions is the preparation of many of his associates for heads of departments of pediatrics in other universities. The enviable position that the Department of Pediatrics at Minnesota now holds among the leading medical schools in America is due to Professor Irvine McQuarrie. Throughout his years at the University, he has maintained a desirable and enviable relation with the general practitioner.

The men in charge of the Pediatric Department of the Mayo Clinic have made many contributions to the progress of pediatrics. The work was first under the direction of Dr. H. Z. Giffin of the Department of Medicine. He was followed in rapid succession by Drs. Archibald, Rood Taylor, M. G. Peterman, who made authoritative contributions to our knowledge of the convulsive state, and Dr. Henry F. Helmholz. The latter became Professor of Pediatrics at the Mayo Foundation and head of this section at the Mayo Clinic. He has written extensively on experimental and clinical pyelitis. In much of his work, he has had as his associate, Dr. Samuel Amberg, one of the foremost scientists in pediatrics. The head of the department is now Dr. R. L. J. Kennedy, a Minnesota graduate. He has made many valuable clinical contributions on different subjects in pediatrics.

Infant welfare clinics were established in the early part of the century in the three larger cities of the state. The work of these institutions has had a direct relation to the reduction of infant mortality. Interns from various hospitals have served under the direction of pediatricians at these clinics with excellent results.

The surgery in infants and children has made vast strides in the last two decades. Many congenital anomalies, formerly resulting in certain death, are often treated successfully in the first days of life. Congenital heart disease with new techniques can now be frequently diagnosed accurately and corrected surgically. Dr. Oswald S. Wyeth of Minneapolis was the first man to limit his practice in surgery to this field. His many contributions and demonstrations in the operating rooms have placed this specialty in pediatrics on a firm foundation in our state. Dr. T. C. Chisholm, during the few years he has been in this field, has also made many contributions and played an important part in the development of pediatric surgery.

Progress in the field of pediatrics during the last decades has been too extensive to discuss in detail. The part that immunization has played in the reduction of contagious diseases is well known. The use of sulfanilamide drugs and later of other antibiotics have proved effective in a large number of infectious diseases. Congenital syphilis is practically eliminated. Childhood tuberculosis is seen rarely. Meningitis of many types is now susceptible to treatment. Allergic disorders can often be treated with excellent results. Progress in the study of poliomyelitis has been rapid and we are now apparently on the threshold of important new methods of prevention and treatment. The list of diseases that formerly caused the high morbidity and mortality rate of infants and children has been decreased. Many of the more serious diseases have been eliminated through fundamental discoveries relating to the causes of disease and the development of definite therapy. The results of all this is apparent in the report of Dr. Robert Rosenthal on "Infant Mortality in Minnesota," published recently in this magazine. As a great majority of sick infants and children are treated by the general practitioner, it is quite obvious that they, as a group, are familiarizing themselves with the advances and research in pediatrics and the newer techniques of examination and treatment of their patients.

Progress in the field of pediatrics in Minnesota has been intimately related to the ideals, accomplishments, and personalities of many pediatricians. Since the beginning of the Golden Age of Pediatrics in the latter part of the 19th century, no branch of medicine parallels this movement aimed at finding some of the answers to the problems relating to the cause of disease and the better distribution of new methods and medical knowledge.

AVERAGE PHYSICIAN WRITES 2,500 PRESCRIPTIONS A YEAR

The average physician in private practice today writes 2,517 prescriptions a year, or one for every three patients.

This is revealed in the March issue of *Medical Economics*. The magazine is publishing the results of a nationwide survey of medical practice, based on a questionnaire sent to each of its 134,000 physician readers.

The survey suggests that the amount of prescribing a doctor does may be substantially influenced by the length of time he has been in practice. At any rate, the young doctor (one with less than ten years' experience) tends to write about 70 per cent more prescriptions a year than the medical man with thirty or more years' experience—even though both men treat about the same number of patients.

The following table breaks down physicians' prescribing habits by community size:

Community Size	*Prescriptions Yearly by Average M.D.*
Under 5,000	2,824
5,000-49,999	2,948
50,000-499,999	2,508
1,000,000 and over	1,848

Medical Economics also investigated the extent of dispensing by physicians. It found that 45 per cent of the doctors surveyed dispense some or all of the medicines they tell patients to take; these dispensing physicians dispense, in the aggregate, 35 per cent of all the drugs they prescribe.

MODERN OTOLARYNGOLOGY AS A SPECIALTY

LAWRENCE R. BOIES, M.D.
Minneapolis, Minnesota

PROBABLY there is no specialty that has undergone so much change because of modern progress in the control of infection as has the specialty of otolaryngology. This change has occurred in the past fifteen years. Prior to that time, the complications of infection in the upper respiratory tract were almost constant problems of the otolaryngologist, particularly in the winter and spring months. Today, acute mastoiditis needing surgery, phlebitis or thrombosis of the lateral sinus, meningitis or brain abscess from ear or sinus infections, osteomyelitis of the frontal bone, or of the maxilla, the peritonsillar and pharyngeal abscess formations, and obstructive laryngitis are relatively uncommon and in some places rare in occurrence.

In spite of this change, chronic infections of the middle ear and mastoid are still seen in considerable quantity. One of the reasons for this is the fact that chronic inflammation in this structure is not necessarily dependent upon an acute process as a precursor, but rather upon the type of mucosal lining involved. When there is a poor pneumatization of the temporal bone either through hereditary factors or neonatal infections, this mucosa tends to be hyperplastic and poorly resistant to infection. In this circumstance an infection reaching the middle ear may be destined to chronicity from its beginning.

Another factor in the development of chronic infection in the temporal bone seems to be the current use of antibiotic therapy without consideration for drainage when secretion has formed in the middle ear and mastoid.

Though these changes in the incidence of complications of infection in the upper respiratory tract have occurred, the specialty of otolaryngology has through new advances developed so many activities that it is difficult for anyone to be entirely competent in all phases of the specialty. This will be apparent if one examines in detail some of the modern activities in otology, rhinology and maxillofacial conditions, laryngology, and broncho-esophagology.

Otology

Surgery on the temporal bone is now performed with much greater skill than it was a decade or two ago. Probably there is no more exacting surgery in any field of medical practice than the fenestration operation for clinical otosclerosis. It was through the development of this operation that temporal bone surgery improved. The otolaryngologist who equips himself to do this work usually finds a broad opportunity to apply the fundamentals of this technique in the surgery of otosclerosis, to chronic suppurations, and to the less common conditions such as atresia of the external auditory canal and in certain cases of endolymphatic hydrops, when surgery is indicated.

There is, of course, a large field of activity in otology that is not surgical. In spite of marked improvement in the control of the acute infections that contribute to hearing loss, the total incidence of this impairment seemingly has not diminished. Probably this is because the incidence from some of the causes has increased in modern times. One is the hearing loss due to acoustic trauma in the form of industrial noise. Also, it seems that the incidence of hearing loss due to a serous otitis media may be more common than formerly. This condition may be caused by an acute interference with ventilation of the middle ear from tubal closure. This results in a transudation of serum. Or, an exudate develops in the middle ear as the result of inflammation or allergic phenomena. Unrecognized and untreated, fibrosis and adhesive processes develop in the mucosa. This may contribute to a permanent loss of hearing of a moderate degree.

Some of this apparent increase in the incidence of hearing loss may be due to the fact that modern methods of testing and the widened use of these tests have revealed more instances of hearing impairment. The audiometer is now widely used for screening tests in schools and as a part of pre-employment physical examinations.

The application and interpretation of modern clinical tests for hearing, and the rehabilitation of those whose hearing loss cannot be helped by medical or surgical means constitutes in itself a large field of activity. Though a considerable part of this work need not be carried on by a clinician, he must give it direction and some supervision.

In addition, he must assume responsibility in advising preventive measures to lessen the incidence of some causes of perception deafness.

A new insight into inner ear problems has developed in the last decade. Vertigo, tinnitus and perceptive loss are common symptoms and seem to be on the increase. In many instances, these symptoms can be interpreted in terms of neurovascular phenomena. This has opened up a fascinating field of inquiry and emphasized to the otologist the importance of a broad knowledge of fundamental physiology.

Rhinology

The fact that acute infections of the upper respiratory tract caused by pyogenic organisms can now be so well controlled means that the modern rhinologist is not confronted with as much suppuration in the nasal space as he was a decade or two ago. Nevertheless, symptoms related to the nasal space are still very prevalent and probably as common as ever. Head pain, congestive states and hypersecretion in the nasal space are daily problems to the rhinologist. Some instances of these symptoms result in some degree from the stress and strains of modern living. Neurovascular phenomena as a factor in head pain and congestive states not dependent on inflammatory processes have been clarified through the work of numerous investigators. The modern rhinologist interprets the vasomotor changes occurring in the nose as the result of allergic phenomena, or as the result of one or more of a variety of human experiences much more accurately than was the case when his training was focused on surgical opportunities.

This does not mean that there is no place for rhinologic surgery. Nasal injury from trauma has certainly not decreased. Skill in the correction of deformities of the external nose and particularly in the deformities of the dislocated nasal septum has increased. The rhinologist who is trained in the fundamentals of plastic surgery and who has a knowledge of and experience in the management of defects in nasal respiration is ideally equipped for the management of these abnormalities. Likewise, this is true of maxillo-facial injury.

There are conditions in the nasal sinuses requiring highly developed technical skill in their surgical management. These are such conditions as the subacute or chronic antrum infection requiring an intranasal antrostomy, the ethmoid state in which exenteration for chronic infection or polyposis is advisable, certain chronic sphenoid or frontal sinus suppurations, osteomas, mucoceles, and malignant disease in various parts of the nasal space.

Laryngology and Broncho-esophagology

The "throat" is the domain of the trained otolaryngologist by right of technical skill and experience in managing the numerous disorders creating symptoms in this area. Here the most common activity from the standpoint of incidence is tonsil and adenoid surgery. Historical accounts indicate that the surgical treatment of the tonsil dates back nearly 3,000 years, yet this subject is controversial today. Two facts probably account for the differences of opinion. The first is that the removal of tonsils and adenoids is often recommended from superficial observation. Secondly, it is considered to be a minor operation and for that reason is undertaken by those who have not acquired skill and training in working in this area. This could account for the fact that in terms of end results, this surgery may not produce the benefits expected, that it is often inadequately done, that the morbidity associated with the operation may be quite significant and that even mortality occurs. The most difficult part of this surgery may be the management of the lymphoid tissue of the nasopharynx in children where particular attention must be paid to the lymphoid folds laterally that obstruct the choanae to produce continued mouth breathing even though the central adenoid mass is removed, or contribute to middle ear disease through blockage at the Eustachian orifices.

Though the modern laryngologist sees relatively few of the abscess formations that once were common in the throat and rarely encounters luetic or tuberculous conditions in an ordinary practice, the incidence of patients who complain of throat symptoms seems to be on the increase. This means that the skilled laryngologist must possess a broad understanding of the various phenomena that might produce vague throat symptoms without local objective evidence of disease, as well as an ability to detect the early changes in malignant disease. He must possess a knowledge of psychosomatic possibilities and the symptoms associated with the tensions of modern living, the phobias that can easily develop through the propaganda for the early detection of cancer, and the neurovascular phenomena producing pain along vascular pathways. No one is better equipped for this than the laryngologist who in training and experience can use the instruments for a complete visualization of the pharynx in both its upper and lower extents, and correctly interpret his findings.

The incidence of laryngeal neoplasms has certainly not decreased. Benign tumefactions of the vocal cords are common and if skillfully handled result in the restoration and preservation of a good voice. Malignant lesions can now be eradicated in a high percentage of cases with good conservation of function. Even when a total removal of the larynx is necessary, the modern developments in speech following laryngectomy offer satisfactory means of communication.

In advanced cases of carcinoma involving the larynx and lower pharynx many lives can be salvaged because modern anesthesia and supportive care, plus new surgical skills, have made a radical removal of these extensive malignant lesions possible.

The modernly trained otolaryngologist is equipped to treat practically all the soft tissue conditions in the neck, exclusive of the thyroid gland. The latter is not included in most training programs even though the more formidable undertaking of total laryngectomy with neck dissection is, and in this procedure the thyroid gland has to be handled surgically as well as in certain cases in which a tracheotomy is performed.

An arytenoidectomy for relief from the respiratory obstruction in bilateral vocal cord paralysis is one of the advances of modern laryngology. The operation is a relatively minor one; an adequate air way can be provided with preservation of a useful voice.

Obstructive laryngitis seems to be less common today than before the advent of the sulfonamides or antibiotics. The employment of these drugs in the environment of high humidity in a controlled temperature has lessened the need for relief in the form of tracheotomy. Often, however, the diagnostic interpretation of an examination by a trained laryngologist is highly important.

Education seems to be lessening the incidence of foreign bodies in the air and food passages, and the skills of the experienced broncho-esophagologist have decreased the seriousness of these accidents. However, the diagnostic procedures related to endoscopy in suspected pulmonary or esophageal disease are more commonly employed. Accurate bronchography, the visualization of obscure lesions through telescopic lens inserted through the bronchoscope, and the early detection of malignant disease are accomplishments of modern broncho-esophagology.

In spite of the progress that has been made, otolaryngology has many unsolved problems. In this challenge there is an appeal. Researches by Minnesota otolaryngologists have made a solid impact on the trend of this specialty. Notable among these have been the contributions of Anderson Hilding, Jerome A. Hilger and Henry L. Williams.

ORGANIZED MEDICINE IN MINNESOTA

(Continued from Page 331)

accord with the practice of a number of forward-looking state associations and large county societies all over the country that were engaging trained lay secretaries to carry on their work.

Today, the Minnesota State Medical Association stands, at its centenary, in a position of organized strength and power which could hardly have been dreamed of on that July morning in 1853.

But the objectives of that hardy handful of pioneers, as expressed in the first constitution adopted that day, do not differ greatly in expression or content from the objectives of the doctors of Minnesota in 1953.

They read as follows:

> "To advance medical knowledge, to elevate professional character, to protect the interests of its members, to extend the bounds of medical science, to protect all measures adopted to the relief of the suffering and to improve the health and protect the lives of the community."

OPHTHALMOLOGY IN THE PAST CENTURY

ERLING W. HANSEN, M.D.
Minneapolis, Minnesota

THE PAST CENTURY has seen the development of medicine and surgery to a very high degree. Ophthalmology has shared in this general advance in pathology and bacteriology, biochemistry, anesthesia, and roentgenology and other diagnostic aids, therapeutics and surgical techniques. Even during the professional lifetime of some of us, there have been such great changes as to seem as incredible to recent graduates as the fact that we had no automobiles, aeroplanes, radio, or movies in our early days.

Just over one hundred years ago, 1851, Hermann Ludwig von Helmholtz described his "eye mirror," the great grandsire of our ophthalmoscope. This relatively crude instrument of silvered mirrors, with which light was reflected into the eye from candle and gaslight, gave the inventor and fellow ophthalmologists an opportunity of seeing the eye grounds and studying the changes therein. After Edison, the light source became the electric bulb until every medical student is familiar now with the modern instrument with its self-containing light. It is probably true that the development of the ophthalmoscope was one of the greatest advances in ophthalmology.

During this period there have been a number of additions to the armamentarium of the ophthalmologist which have greatly aided in the study of eye diseases. Among these is the perimeter of Foerster in 1868 and the tangent screen, which Albrecht Von Graefe made on wood in 1855, followed by Bjerrum's cloth screen in 1889. As the ophthalmoscope had made possible the detailed study of the posterior portion of the eye, so the combination of corneal microscope introduced by Abbe in 1881 and the slit-lamp of Gullstrand, 1911, has given the opportunity for study of minute details of the cornea, anterior chamber, lens, and anterior vitreous. A further more recent development of the contact lens, as well as the Allen prism, has made visualization of the angle of the anterior chamber possible, very important in the problem of glaucoma.

While there had been much knowledge accumulated in respect to physiologic optics during the preceding centuries, it is probably safe to say that the period of accurate refractions of the eye had its real start with the advent of the ophthalmoscope. The first measurement of refractive errors with this instrument is credited to Edward Von Jaeger in 1855, followed by Bomans skiascope in 1859. Our retinoscope, one of the most important instruments in accurate refraction, stems from this "shadow test" study. The test charts for visual acuity in general use today are those of Snellen, introduced in 1862. The near vision test card is that of Jaeger from 1867. Donders published his epoch-making book, "The Refraction and Accommodation of the Eye" in 1864 and Helmholtz's "Textbook of Physiologic Optics" in 1856-1867. The trial-case of lenses was invented by Fromuller just before this era, 1843, but it was many years before ophthalmologists, as such, had trial cases, or for that matter, did many refractions. This was largely a matter left to opticians. In this country we owe much to Edward Jackson, for his interest and teachings in refraction as well as other phases of ophthalmology.

The problems of ocular motility as well as those of refraction were not well understood even in the days of Von Helmholtz and Von Graefe. Javal, in 1868, was responsible for the beginnings of our present concept of anomalies of ocular movements. Among others are Claude Worth and Maddox in England, Stevens, Savage, Duane, and Lancaster in this country, and more recently, Bielschowsky who came to America after working in Breslau for some years. The causes and correction of strabismus and motor anomalies are being given a large place at the present time in ophthalmological discussions.

It is during this period of time that a fuller knowledge of gross and microscopic anatomy of the eye has constantly been attained and with this naturally a better understanding of pathological processes. In connection with the latter, the name of Ernst Fuchs, of Vienna, at whose feet some of us have had the privilege of sitting, probably should head the list. In England there was Sir John Parsons and Treacher Collins. If we were to pick one man above all others in this country it would have to be F. H. Verhoeff of Boston. There are a great many younger men, and for the sake of accuracy, women, who are furthering this valuable work. It should be recorded also that while, until recently, few ophthalmologists were conversant with the subject of histopathology, the graduate student in our field has been, in the recent past, gaining a very good working knowledge of it.

If an attempt were made to any more than catalogue the tremendous change in the etiological status of eye diseases, there obviously would not be space in a paper of this kind. What it meant may be quickly gathered by a very few dates—the discovery of the gonococcus of Neisser, 1879; staphylococcus, Ogston, 1881; tubercle bacillus, Koch, 1882; pneumococcus, Friedlander, and Klebs-Loffler bacillus, both in 1883; tetanus bacillus, Nicolaier, and the streptococcus, Rosenbach in 1884; and the spirochete of syphilis in 1905. If the increased knowledge in bacteriology and virology since that time were added, we would surely have a large volume.

Some of the above-mentioned organisms have been the cause of many of our severest eye lesions and the most destructive of sight. One of the leading causes of blindness in children was for many years, interstitial or parenchymatous keratitis. Jonathan Hutchinson, in 1858, showed that condition was one of the stigmata of congenital syphilis, along with notched teeth, and nerve deafness (Hutchinson's triad.) In recent years, where pre-natal treatment of syphilitic mothers has been in effect, especially in the first trimester, the incidence has dropped to almost nothing. In our state, it is very evident in the Faribault school, where it has dropped from a high to a low percentage of the blind or visually handicapped.

Another severe and blinding disease, responsible for many children in special schools, was ophthalmia neonatorum, gonorrheal ophthalmitis. In 1881, Crede introduced the method of prophylaxis known by his name, i.e., the instillation of silver nitrate in the eyes immediately after birth. The incidence dropped in all places where it was used from about 10 per cent to less than 0.5 per cent. Since the advent of penicillin there has been a sustained effort on the part of some to substitute this antibiotic for the 1 per cent silver nitrate solution now mandatory. There has been hesitation in adopting this change with the proven effectiveness of the silver solution. In the few instances in which infection develops, constant improvement in therapy has effectively saved eyes when treated.

Trachoma, which is considered among the viral diseases, is endemic in some countries, particularly Egypt and the near East. Its ravages have been known since earliest times, and have been of such great importance that international organizations have been at work during this century on the study of the disease and its amelioration. The first hopeful reports on treatment have come since the introduction of the sulfonamides.

It is sad to report that with the increasing knowledge of general medicine and with the constant addition of life-saving and life-prolonging measures, in some conditions there is an inverse ratio of visual health. One of the conditions is diabetes. In the younger diabetics, who have survived with the help of insulin, we are seeing more and severer retinopathies, going on in many cases to massive vitreous hemorrhage, retinitis proliferans, retinal detachment and blindness. With older people, too, the disturbances in the retina occurring with diabetes and in combination with hypertension is bringing about much visual loss. There has probably been also an increase in senile macular degeneration with the increase in longevity. Cataract of the senile type and glaucoma obviously would also show an increased incidence.

Another unfortunate condition causing blindness in children has appeared in about 12 per cent of the premature infants who are being saved. This condition, first described by Terry in 1932, and called by him retrolental fibroplasia occurs in greater numbers of prematures whose birth weight is under three pounds, decreasing proportionately as full term is reached, and is not seen in full-term babies. The pathology is now very well known, the end result being a complete detachment of the retina, which becomes incorporated in a fibrotic mass seen behind the crystalline lens. To date no influences in pre-natal or post-natal life can be said to be responsible for the development, the only definite factor being that of prematurity. This has meant that while there has been a decrease in special schools of children with poor vision or blindness from interstitial keratitis and ophthalmia neonatorum, their places are being taken by these unfortunates.

One of the more serious problems of ophthalmology is glaucoma, not a disease entity but a symptom complex. The condition of hardness of the eyeball had long been known, but its nature was not established until after the development of the ophthalmoscope, followed by the perimeter and tangent screne. Measurement of the intraocular tension by means of the tonometer was made by various observers and instruments devised for this purpose. The ones in most common use today are products of the Twentieth century, those of the original Schiotz instrument or its modification by Gradle, and the McClean.

The important thing in glaucoma is its early recognition and relief of the increased intraocular tension. Pilocarpine and physotigmine or eserin were not isolated until the fourth quarter of the last century. It is only in the present century that medical treatment of glaucoma has had any degree of success. In recent years there have been a number of new products developed, which are useful in certain cases, but as yet pilocarpine is probably the one best drug available. The surgical treatment began with iridectomy, which was first done for this condition by Von Graefe in 1855. This method is still effective in a large percentage of cases of acute congestive glaucoma. In 1867, DeWecker proposed doing a sclerectomy, to produce a permanent fistula from the anterior chamber now commonly called the La Grange operation. This has been the underlying principle of all operations since, to produce such a filtering cicatrix. The two most widely used have been the corneo-scleral trephine of Elliot and the iridencleisis or iris inclusion operation of Holth, both developments of this century. As before mentioned, gonioscopy has made possible, in recent years, a view of the angle of the anterior chamber, a great aid in diagnosis, and in the selection of proper treatment. It has also brought about a revival of interest in congenital and juvenile glaucoma and their treatment by goniotomy.

Of the inflammatory diseases of the inner eye, iritis, irido-cyclitis, or generalized uveitis hold an important place. Space will not permit details of the changes that have taken place in our day in the ideas concerning the etiology and treatment of this oftentimes severe condition. In the textbooks of the early part of the century, syphilis was given as the chief cause of iritis. We now divide the disease into non-granulomatous and granulomatous iritis. The list of workers who have investigated the production of this disease experimentally is very large. We owe a large part of our knowledge to the development of the studies of immunity and allergy. Atropine had been used in treatment more than a hundred years ago, and is still an integral part of treatment. Fever therapy, with foreign protein injections, for a number of years, has been a valuable adjunct. Cortisone and ACTH have been of great value in controlling inflammations in certain types of iritis, but ophthalmology has experienced also some of the disappointments which other fields of medicine have had with these hormonal substances.

Ophthalmic surgery, as well as surgery in general, was given great impetus by two developments in the nineteenth century. Shortly before the period under consideration, general anesthesia had been introduced. Prior to this time eye surgery had been done without anesthetics or under some influence of opium or alcohol. It may be possible that the rather general popular idea of pain in cataract surgery has been carried down from that period. The other was the antisepsis of Lord Lister which led to our modern asepsis. A further aid to eye surgery was the introduction of the use of cocaine as a local anesthetic by Carl Koller, an American working in Vienna in 1884. For many years this was the only anesthetic that was used in cataract surgery, and those of us who were doing these operations twenty-five or thirty years ago used topical instillations of 4 per cent cocaine with satisfaction. Other local anesthetics have largely supplanted the use of cocaine. The advent of procaine was another milestone and is much used for infiltration anesthesia, particularly in retrobulbar injections in intraocular surgery. Adrenalin used in connection with anesthesia, was isolated by Takamine in 1900, just as we turned the corner into the present century.

The most commonly performed intraocular operation is that for senile cataract. Naturally this condition had always been observed and from very early times the pupil had been cleared of this "inspissated humor" by couching or pushing it back into the vitreous. This is mentioned because even after the first cataract extraction, generally credited to Daviel in France in 1747, one hundred years of controversy as to the operation of choice took place. It, therefore, brings the era of common acceptance of extraction of the lens to the last hundred years. The early incisions were made in the cornea and it was again

Albrecht Von Graefe who first introduced the linear incision at the limbus. His narrow-bladed knife, the Graefe knife, is still in use today. With many operations, the section is no longer made with the straight knife, the original incision being made with the keratome and enlarged with special scissors to the desired length. Two principle changes have been made in the cataract operation during the past quarter century. The first is the use of corneal or corneo-scleral sutures which are preplaced before opening the eye and tied on removal of the cataract. The second is the extraction of the lens in the capsule, which may be grasped by a toothless forcep or by means of a suction cup. Both of these procedures, in competent hands, have added much to the successful outcome of the operation.

One other surgical development must be added, that for retinal detachment. Various attempts had been made to reattach a separated retina with somewhat indifferent success and most cases of detachment were doomed to loss of sight in the affected eye. At the International Congress of Ophthalhology in Amsterdam in 1929, Gonin reported his operation of "ignipunctur" or electrocoagulation. Diathermy coagulation is now generally done, the principle being the production of multiple spots of irritation which in the process of healing re-cement the detached retina, and close the hole or tear usually present in the retina.

These examples will suffice to show the remarkable changes that have taken place. Mention should be made of the electromagnet for removal of intraocular foreign bodies of steel or iron. The camera for fundus photography has also been developed as an aid in following the progress of a case, and as an aid in teaching. The new developments in chemotherapy and antibiotics are too well known to require elaboration.

This account should not be closed until the great changes in the matter of education and training in ophthalmology have been recounted. It can readily be seen that almost all of the new instruments, the discoveries in basic sciences, the development of new techniques mentioned in this paper came from Europe. There have been many improvements by Americans in recent years. Living ophthalmologists in this country have scarcely been mentioned in this paper. History will take care of them. When the next hundred years is recorded, perhaps American names will lead all others.

Not so long ago men in this country, desiring to specialize in this field, worked with someone who was already in it, or made visits to the larger cities where clinics were established. Many spent time in London and Berlin, a few in Paris, but most went to Vienna. In the middle of the last century and indeed much later many men known as ophthalmologists also did general work. There was a long era, which continues somewhat even today, when a combination of eye, ear, nose, and throat practice prevailed. We are nearly at the end of that period, with training being given in ophthalmology or in otolaryngology. Actually there is more reason for ophthalmology and neurology to be combined than ophthalmology and otolaryngology.

The training of men in ophthalmology today is done mostly in three-year fellowships, as at Minnesota, or in one year spent in basic courses in instruction in certain medical schools, followed by two years of residency in approved hospitals. In addition to the work done by the American Medical Association, the Hospital Associations and the American College of Surgeons in the general improvement of medical schools and hospitals, the American Board of Ophthalmology has been a tremendous factor in the improvement of training in this specialty. This was the first of the specialty examining boards, organized jointly by the Section on Ophthalmology of the American Medical Association, the American Ophthalmological Society and the American Academy of Ophthalmology and Otolaryngology. Dr. Edward Jackson it was who fathered this idea and was the board's first chairman in 1916.

So, with improved tools, with ever-widening knowledge, with greatly improved training of young men, ophthalmology looks back on a hundred years of greater achievement than in all the centuries that had gone before, and forward to a bright future.

DERMATOLOGY IN THE FIRST CENTURY OF MEDICINE IN MINNESOTA

HENRY E. MICHELSON, M.D.
Minneapolis, Minnesota
FRANCIS W. LYNCH, M.D.
Saint Paul, Minnesota

LITTLE can be said of Minnesota dermatology before 1875. That there was little of dermatologic note in the United States is shown by Pusey in his general "History of Dermatology" where he lists only two major American items prior to 1850 and notes that the stirrings of "modern dematology" in Europe between 1850 and 1875 influenced only a handful of Americans as individuals. In Minnesota, except for clinical teaching at the several Medical Schools the story continued to be that of individuals until after 1915. The nature of early dermatologic practice in Minnesota seems not to have differed essentially from that elsewhere, though it is of some interest to note that there were some cases of leprosy among Scandinavian settlers, in number sufficient to attract the attention of the noted Norwegian dermatologist, Carl William Boeck, on a visit in 1869-70 to Minnesota and several adjoining states. Probably due to climatic and hygienic conditions the disease subsequently disappeared from the state.

Several early dermatologists deserve individual consideration. Two Saint Paul physicians were among the earliest members of the American Dermatological Association, yet they can hardly be regarded as dermatologists or even as contributors to Minnesota dermatology; in fact, it is not clear why either of them desired membership in that organization. The death of one, Harry C. Hand (1848-1876), was recorded in the first transactions of the Association. The other, Daniel W. Hand (1834-1889), was an outstanding, able, and highly regarded physician of wide interests and activities but it is not known that he contributed directly to dermatology here or elsewhere, though he was the first president of Ramsey County Medical Society and also the first president of the State Board of Health.

Minnesota dermatology was early favored by the attention of a little-remembered, but active and peripatetic figure, LeGrand N. Denslow (1852-19??). He had already practiced his specialty from 1880 in New York City as a member of the New York Dermatological Society and was a recently elected member of the American Dermatological Association before his short period of practice in Minneapolis. He moved to Saint Paul in 1885 where he was Professor of Genitourinary Surgery and Venereal Diseases at the Saint Paul Medical College from 1885 until 1888 when the College was absorbed by the Medical School of the University. Denslow left Saint Paul about 1890 and subsequently practiced dermatology in Los Angeles (about 1893) and then returned to New York City until at least 1908. Then, or during his previous sojourn, he was active in the Outpatient Department of Bellevue Hospital. Working in 1909 at Charcot's Clinic at the Salpetriere Hospital in Paris, he became interested in a therapeutic technique which he later publicized in a monograph, "A Surgical Treatment of Locomotor Ataxia," (Balliere, Tindall & Cox, London, 1912). Though Denslow visited in New York in 1910 and 1911 he seems to have practiced in London from 1910, with a Harley Street address for a time. If Denslow left few lasting marks in Minnesota, his subsequent course seems of sufficient interest to deserve listing him in this review.

Throughout this early period the dermatologists divided their interests, with considerable attention devoted to genitourinary diseases. Unlike most, Burnside Foster (1861-1919) seems to have been much more interested in dermatology though, of course, treating venereal diseases, a custom which continued for some time. Coming from the East, he established his practice in Minneapolis in 1887 but changed to Saint Paul in 1891, apparently to take over the practice vacated by Denslow's departure. While many modern physicians have dozed in their offices and many others in earlier days slept there at night, Foster may have been unusual in utilizing in Minneapolis a desk which was converted to a bed at night. He was a learned individual, interested in writing and in teaching, acquiring professorial rank in dermatology at the University Medical School (1899) where he lectured for many years on Medical History as well.

Dr. Michelson is Professor and Director of the Division of Dermatology and Dr. Lynch is Clinical Professor in Dermatology at the University of Minnesota.

He was a member of the American Dermatological Association, attended national and international dermatological meetings, wrote numerous papers for local and national journals, and was active editorially in Minnesota. He was the first president of the Minnesota Dermatological Society. Foster and Vander Horck may be regarded as the first who strongly influenced the course of dermatology in Minnesota though the early years of the twentieth century brought many more who expanded and developed dermatologic practice in this region.

The history of a specialty in medicine in a locality is largely a report of the progress of that specialty in the medical school or schools of the area. In Minnesota the state university now has the only medical school. The history of dermatology at the University may be divided into three periods. The first began about 1900 and continued until 1911. At that time Dr. Max Vander Horck was professor of dermatology and genitourinary diseases. He was trained in Vienna and because of a fascinating personality attracted attention to the teaching and practice of dermatology. At that time dermatology was taught by demonstrating patients with dermatologic conditions and by lecturing upon the disease the patient presented. There was no plan of progressive lectures. There was no hospital service, therefore no interns or residents who could be called upon to investigate the patient. Diagnoses were made at sight. Dermatopathology was not available. What assistance Dr. Vander Horck had came from volunteers, such as Franklin R. Wright, John Butler, and S. E. Sweitzer. They were all influenced by Vander Horck and went to Vienna and other European centers to further their knowledge. On their return they practiced dermatology and treated venereal diseases. They also attended the University dispensary where small groups of students were introduced to the morphologic diagnosis of skin diseases.

After Dr. Vander Horck's death, Dr. S. E. Sweitzer was appointed to be in charge of dermatology. He held the rank of associate professor. In addition to the dispensary clinics, Dr. Sweitzer organized an undergraduate teaching schedule. He had the assistance of Drs. John Butler, Harry Irvine, George Olson, and Clifford Boreen, all of whom were practitioners. There were no postgraduate students. When the University Hospital was opened Dr. Sweitzer became the first dermatologic consultant. Dr. Sweitzer was in charge of dermatology for approximately another, or the second, decade of the specialty at the University. About 1920 Dr. Sweitzer was given the opportunity to establish dermatology at the Minneapolis General Hospital, where he developed a large out-patient department and was assigned a certain number of beds in the hospital. The teaching at the University was entrusted to a committee consisting of Drs. Butler and Irvine; this policy continued until the present incumbent, Dr. Henry E. Michelson, was put in charge and in 1925 he was made professor of dermatology. He was a product of training under Dr. Sweitzer and a European sojourn. Dr. Irvine had previously exhibited great interest in the public health aspects of venereal diseases and subsequently spent many years of part-time work in this field at the Minnesota Department of Health.

The history of the specialty at Minnesota is essentially the same as the history of dermatology in America, beginning with the end of World War I to the present time. It may be briefly outlined as follows: Previously there was practically no place in America where a graduate student could receive adequate training in dermatology. Vienna, Paris, Berlin and London offered such instruction. Vienna had the best organized teaching and therefore attracted physicians who wished to take postgraduate training. Dermatology was well established throughout Germany, Austria, and Switzerland by 1910. The founders of dermatology in the various centers had created their particular schools. Successors had ascended to the professorships and the staffs included many assistants and residents. Some of these posts were open to Americans who, if appointed, became indoctrinated and inspired to go beyond the routine lectures. These few visualized transplanting such ideas to America, but on returning they found the medical faculties quite loath to further their lofty plans. The facilities were and still are lacking, and the enthusiastic embryo dermatologist had to indeed have zeal to continue to adhere to his intentions and fight the opposition. This was about the condition of dermatology at the end of World War I. There were many European trained men in the larger cities; most of them had some university connections; most of them had secret plans to build departments if the opportunity presented itself. They depended for their clinical help upon the young men returning from European clinics, but the war had disrupted European teaching. Glorious Vienna was no more the capital of a large empire with royal support. Young men had to turn to their own schools for graduate training. Dermatology, like the other specialties, had been organized for undergraduate teaching. Now it found men pounding at its door for training. The University of Minnesota was in the same position as other similar institutions. It was emerging from the predominantly undergraduate phase to one of combined or continued undergraduate and graduate instruction. Dermatology took its place with the others. Services were established at the University, the Minneapolis General and the Ancker Hospital. Lectures, demonstrations, courses in other departments, were utilized. A framework of graduate instruction was built. The work at the University was parallel to the work at the Mayo foundation. Graduate degrees were granted on fulfillment of the requisites.

When the Board of Dermatology and Syphilology was established, Minnesota was chosen to be one of the accredited schools, having met the requirements.

The history of dermatology in Minnesota has been one of steady, gradual growth. Dr. Michelson has been in charge since 1925. The staff at present has one professor, two clinical professors, two associate clinical professors, two assistant clinical professors and a number of instructors, assistants and residents. Dermatology at the Minneapolis General, Ancker and Veterans' Hospitals are intimately associated with the University in the graduate program.

The dermatologic staff have received recognition. There has been one president of the American Dermatological Association and of the Investigative Society for Dermatology, two chairmen of the Section of Dermatology of the American Medical Association, two members and one president of the American Board of Dermatology, and three presidents of the Chicago Dermatological Society. There have been two corresponding members of the Austrian Dermatologic Society and one honorary member and one corresponding member of the British, Danish, Swedish, Italian, and French Societies. There have been innumerable contributions to dermatologic literature and to society programs. The future of dermatology at the University of Minnesota will undoubtedly keep pace with the general progress of the school.

In much lesser degree has Minnesota dermatology been influenced by two organizations other than the Medical School. Founded in October, 1915, the Minnesota Dermatological Society continues actively with a program of clinical presentations, open discussion and an informal dinner. There were at its initial meeting five from Saint Paul: Armstrong, Cook, Foster, Freeman and Klein; five from Minneapolis: Butler, Olson, Sweitzer, Thomas and Wright; and Linneman from Duluth. The first elected officers were Foster, president, Sweitzer, vice president, and George Olson, secretary. The meetings have alternated between Minneapolis and Saint Paul, with less frequent meetings in Rochester and Duluth. It is among the oldest of America's local dermatological societies. Transactions were published only by several groups in New York City, one in Philadelphia and one in Chicago when the Minnesota Society began such publication in 1916, since when the transactions of the Society have been published regularly in the *Journal of Cutaneous Diseases* and its successor, the *Archives of Dermatology and Syphilology*. Today the organization is of regional stature with active members in Wisconsin, Iowa, Nebraska, the Dakotas and Manitoba.

Most of the early members of the Minnesota Dermatological Society continued practice in the area. The Minneapolis men have already been mentioned. In Saint Paul, John Armstrong was a man with a wide range of interests, including editorial activity, library work, Minnesota history and archery. Teaching activities of Henry ("Nick") Klein and Charles D. Freeman, Sr., were largely confined to work in public clinics in Saint Paul. Freeman was a regular attendant at meetings of the American Dermatological Association, invariably acompanied by Jack Butler, a close friend of many years. Edward T. Gager subsequently joined the Society and practiced in Saint Paul for many years.

In dermatology as in other fields of practice, the Mayo Clinic has exerted a favorable influence in Minnesota. There was no separate dermatologic service at the Clinic prior to 1916 when John H. Stokes arrived to head such a Section. Though he did not directly exert much influence on Minnesota dermatology during his relatively brief stay, he did bring to the Clinic a young associate, Paul A. O'Leary, who succeeded him as Head of the Section and has since been an inte-

A HUNDRED YEARS OF PROGRESS IN THE THERAPY OF URINARY INFECTION

WILLIAM F. BRAASCH, M.D.
Rochester, Minnesota

UP TO 100 years ago the therapy of disease in the genitourinary tract consisted largely of treatment for stone in the bladder, stricture of the urethra and venereal disease. In common with other branches of medicine, urology was on the threshold of a new era. The leaven of scientific investigation, which had been slowly maturing, burst forth with one discovery after another which revolutionized the practice of medicine in all its phases.

When the methods of treatment in use a century ago for infection in the urogenital tract are compared with modern methods of treatment, the vast progress that has been made since that time can be realized. Knowledge of such infection 100 years ago was extremely meager. Uroscopy, employed as a method of examination of the urine since the medieval era, was still being used. The modern instruments of diagnosis and the exact methods of study of the urine employed today were then very remote. Use of the microscope in examination of the urine was unknown. Localization of the source of pyuria was largely guesswork. The practitioner of that day might allow the urine to sediment, and thus gain some impression, from its appearance, as to the presence of pyuria. If dysuria was present, the physician of that time probably would have prescribed one of the drugs commonly used for that purpose, such as sodium bicarbonate to alkalinize the urine, spirits of niter or sandalwood oil. If pain was present, he probably would add laudanum or paregoric.

The best-known type of urinary infection at that time was that which occurred secondary to stone in the bladder. By inserting probes through the urethra into the bladder, the physician could ascertain the presence or absence of stones. If stones were present, removal was attempted either by means of crushing with the crude instruments extant or perineal lithotomy.

Theory of Bacterial Infection

Modern concepts of infection began with the discovery of Pasteur that infection is caused by bacterial invasion of the tissues. This discovery also opened the way for the modern therapy of infection. Realization of the value of Pasteur's theories and their application to the therapy of urinary infection by the medical profession was unbelievably slow. For instance, the febrile reaction which often occurred after the passage of unsterile instruments in the urethra was believed to be caused by absorption of decomposing urine, and was referred to by clinicians of that time by the facile French term, *absorption urinaire*. Strangely enough, Pasteur's discovery of bacterial action was not generally accepted by many of his contemporaries. The discovery of the tubercle bacillus by Robert Koch, and its demonstration as the cause of tuberculosis came later. Various followers of both Pasteur and Koch subsequently identified the causative bacteria involved in different types of infection.

The vast work of identifying and classifying the many hundreds of bacteria which cause disease proceeded gradually, but recognition of the bacteria involved in urinary infecton was extremely slow in developing. In fact, it was not until recent years that the distinction of bacteria and adequate methods of treatment were evolved. Nonetheless, even in early years it became evident that elimination of urinary infection depended on a working knowledge of the bacteria involved. Today the urologist readily gives the names of a multitude of bacteria and is familiar with many of their cultural characteristics and microscopic appearance.

The next step to intelligent treatment of urinary infection was the necessity not only for a working knowledge of the bacteria involved, but also for recognition of their individual reactions to the various bactericidal drugs. Even today, it will not avail to dust off and read old textbooks on bacteriology to obtain such information, because knowledge of the subject is constantly being revised. What is required is to consult current literature to bring oneself up to date.

Urologists found that microscopic examinations of dried urinary sediment stained with Gram's stain permitted a practical and fairly accurate method of identification of bacteria. They also

---

Dr. Braasch is an Emeritus Member of the Section of Urology, Mayo Clinic, Rochester, Minnesota.

called attention to the frequent occurrence of two or more different types of bacteria in an instance of urinary infection. This, in turn, called attention to the need of identifying the several organisms present before selection of therapy.

Rise of Rational Drug Therapy

The therapy of urinary infection a century ago was limited and empirical, and it remained so for many years. Pasteur's work, once it came to be accepted, provided the opportunity for scientific investigation of antibacterial drugs. Although progress was extremely slow until recent years, numerous attempts were made with various means to combat the infecting bacteria. Following the example of Koch and his co-workers in the field of tuberculosis, attempts were made to eliminate urinary infection with vaccines, both autogenous and otherwise. Although good results occasionally were reported, such attempts were largely unsuccessful.

Bacteriophage, which had been found to be of some value in combating cholera, also was tried in eliminating urinary infection caused by B. coli. Although some favorable results were reported, the method gradually fell into disuse. A number of chemical preparations administered orally were employed with variable results. Prominent among these should be mentioned hexamethylenamine. This drug was widely used as a urinary antiseptic agent under the trade name of urotropin. Hinman showed that this drug was of little therapeutic value unless the pH of the urine was less than 5. When used with drugs that acidify the urine, hexamethylenamine still is employed in controlling infection with B. coli, since it causes little or no systemic reactions. Several preparations of azo dyes were employed in an effort to combat acute renal infection. Hugh Young advocated the intravenous injection of mercurochrome. In several cases the fever subsided within twenty-four hours after mercurochrome had been injected, and the infection was miraculously controlled. However, in many other cases little or no benefit resulted, and several deaths were reported as following intravenous injection. Other dyes were used for chemotherapy, including acriflavine and gentian violet, with similar results. The intravenous injection of neoarsphenamine in minimal doses eliminated urinary infection with staphylococci in some cases. A great variety of drugs was used for local application to infected areas of the urinary tract by means of lavage and instillation. Among them, solutions of silver nitrate, potassium permanganate, silver protein preparations and mercurochrome were most frequently employed for urethral instillation and lavage of the bladder and the renal pelvis.

One of the notable attempts to control bacillary infection was made by Nielson, a Swedish scientist, who found that acidification of the urine to a pH of less than 5 would eliminate colon bacilli. However, it proved to be difficult to maintain a lethal acidity of the urine by oral medication. About this time Helmholz noticed that a glass of urine which had been standing in the laboratory for five days remained clear. He found that it belonged to a patient being treated for epilepsy by means of a ketogenic diet. It was evident that the urine produced after a ketogenic diet contained elements which were bactericidal. Clark thought that the sterilizing element in such urine was largely that of acidification, and found that the diet eliminated bacilluria in a series of patients who had urinary infection. Later, Fuller showed that the important bactericidal element in ketonuria was an end product of fat metabolism, namely, beta-hydroxybutyric. However, many patients found the ketogenic diet very objectionable, particularly when continued over a period of several weeks. Fortunately, about this time, Rosenthal discovered that mandelic acid, when excreted in the urine, would eliminate bacilluria. The ketogenic diet was rapidly displaced by the use of mandelic acid, which was widely employed in a synthetic form. After a few years, however, this drug in turn was supplanted by the sulfonamide and antibiotic drugs.

The therapy of urinary infection as employed today had its inception in the brilliant research of Domagk, eighteen years ago. He was first to discover a drug which when absorbed caused a bactericidal reaction in the tissue cells. His first sulfonamide drug, called prontosil, initiated the development of a series of drugs which revolutionized the therapy of infections. The group of sulfonamide drugs multiplied rapidly, so that today there is a wide choice of those which have specific action in urinary infection. These drugs in turn, in recent years, have been succeeded by the development of antibiotic drugs, so widely employed today.

It has been said that there is a drug for every bug. While this is not strictly true, there are specific antibiotic agents and sulfonamide drugs for the various bacteria involved in urinary infection. Intelligent use of these agents requires a careful study and a thorough knowledge of bacteriology as well as of the varying reactions on the part of bacteria to the different drugs employed. It must be remembered, moreover, that all of these agents are most efficacious when the infection is largely superficial, when there is no extensive cicatricial change in the renal tissues and when there is no obstruction to drainage of urine.

Fancy might lead one to visualize the treatment of infection in the future. It might be wondered whether the therapy employed 100 years from now will cause the status of therapy of today to appear as primitive as that employed a century ago.

Renal Tuberculosis

The modern conception of renal tuberculosis, as well as treatment of the disease, had its origin with the discovery of the tubercle bacillus by Robert Koch. The attempts made by him and his followers to overcome pulmonary tuberculosis by means of vaccine also were applied to renal tuberculosis. Similarly, there was no success. It took many years after the first successful nephrectomy by Simon in 1869, before attempts were made to remove the kidney because of tuberculosis. In the meantime, it had been discovered that the diagnosis of renal tuberculosis could be made by detection of the tubercle bacillus in the sedimented urine and, later, by cystoscopy. The mortality rate associated with nephrectomy was gradually reduced from 50 to 2 per cent. The methods of treating the infected ureter varied from ureterectomy, partial or complete, to injecting it with phenol. It also came to be realized that the auxiliary treatment of rest and adequate nutrition were of value in the attack on renal tuberculosis. No method of chemotherapy which was tried proved to be of any value until recent years, when it was found that streptomycin deters the growth of Mycobacterium tuberculosis. This particular development has presented some basis for hope in the chemotherapeutic elimination of tuberculosis in all its forms.

Gonorrhea

Gonorrhea was known to the ancients. It has plagued humanity over the centuries. For ages the bacterial nature of this disease was unknown, and as a consequence of absence of such knowledge, treatment defied the theories of all physicians and savants. It may be said that the modern conception of gonorrhea began in 1879, when Neisser demonstrated that the coccus which bears his name is the cause of gonorrhea. Even with this knowledge at hand, treatment of the disease remained unsatisfactory, and was the subject of wide controversy for several years. Although lavage of the urethra with potassium permanganate, silver protein preparations and solutions of silver nitrate often relieved the symptoms, it did not eliminate the infection. A curious therapeutic development arose when Carpenter and his colleagues discovered that the gonococcus succumbs when subjected to a temperature of 106° F. Cabinets were constructed in which patients could be subjected to a temperature of 106° to 107° F. for several hours. Desjardins and his colleagues reported on a series of patients treated in fever cabinets, from whom the gonococcus was completely eliminated. This meant that, although the treatment was heroic, it was the first that could completely eliminate gonococcic infection which had defied all previous efforts for centuries. Shortly after the introduction of fever therapy, it was shown that the sulfonamides could accomplish the same thing. These drugs in turn were soon succeeded by antibiotic agents, which are being employed so widely today.

Within a few years a simple and successful treatment of gonorrhea has been found. The entire clinical picture of this disease has been revolutionized. Many complications of chronic urethritis which plagued the urologist over the years have vanished like magic, and bid fair to be relegated to the past. As successful elimination of the gonococcus has been attained, many of the social complications, as well as most of our previous concepts, of the disease have gone. With the recent development of so-called one-shot methods of the administration of antibiotic agents, the incidence of stricture of the urethra, which plagued men over the centuries and once seemed to support the urologist in his practice, now promises to become scarce, if indeed not eliminated. In fact, it looks as if the future urologist will face a strictureless world.

MINNESOTA OBSTETRICS
1853-1953

WILLIAM P. SADLER, M.D.
Minneapolis, Minnesota

THIS YEAR marks the hundreth anniversary of the Minnesota State Medical Association and it has become the writer's privilege to give a historic sketch of obstetric progress in our state during the past century.

The Minnesota Territorial Medical Society held its first meeting on July 23, 1853. Like some newborns, the society had a faltering start. Few meetings were held. Reorganization was attempted in 1856. It was not until 1869, following the turbulent civil war period, that the State Medical Society as we know it today, was reorganized.

Our Minnesota State University opened in 1851. Professor E. W. Merrill was its head. Twenty students were enrolled. The University was discontinued in 1855. It reopened in 1867. William Watts Folwell was its first president. The University's early years were fraught with many difficulties. After the civil war, its one building was found occupied by a squatter. Turkeys and cordwood were housed in different rooms. Its basement was badly damaged by wood chopping.

It is a far cry from the University's turkey roosting days and enrollment of seventy-two students in 1867 to the vast acreage, enormous physical plant, and teeming thousands of enrollees today.

The story of medical and obstetrical progress over the century is largely the influence of the University on medical education. Our great University has been the lode star in our attainments. Its greatest gifts have been not what the students were offered in fine buildings and equipment, nor in didactically imparted knowledge of facts. The influence it exerted in the development of character and native ability in its students has been worth more than all else put together. Dr. Jennings C. Litzenberg's greatest of many accomplishments in Obstetrics and Gynecology, as head of the department (1913-1938), was his influence on the development of these traits in his students.

Obstetrics is that branch of medicine which deals with parturition and its sequels. Its chief aim is that every pregnancy ends with a healthy mother and child. Obstetric care strives to reduce discomfort and to leave mother and child physically and mentally sound.

The earliest obstetricians were women and priests. For thirteen centuries the physicians of Europe were not allowed to attend normal cases of delivery. In the seventeenth century they began to participate to some extent. Obstetrics was not a man's profession in America until the middle of the nineteenth century. Our story of Minnesota Obstetric progress begins at this time.

In the last century Minnesota's physicians printed cards in the newspapers indicating their availability for "complicated obstetric cases." Many of the midwives in our pioneer days had been trained in good schools of midwifery in Holland, Germany and the Scandinavian countries.

Preventitive obstetric medicine is considered an American contribution to the widespread introduction of prenatal care. Much credit is given John William Ballantyne, a University of Edinburgh graduate in 1883 for his advocacy of antenatal care. In our country it was conceived in 1901 by the Boston nursing profession and received great impetus in 1912 by Robert deNormandie.

Dr. Mary Jackson Whitney practiced in Rochester, Minnesota, during the years 1879 and 1880, three years before Ballantyne's graduation. Her card published in a Rochester paper of the day read:

> "Ladies if you intend to secure services of Dr. Whitney during your confinement, engage her at your earliest convenience. Twenty years' experience as midwife causes her to prefer visiting her patients before the event as well as after, in order to render the occasion comfortable and safe. Her subsequent visits are to insure as far as possible perfect health combined with an elegant figure. No extra charge for advice."

Dr. Whitney's advocacy of prenatal care in Minnesota antedated by many years, the famed Ballentyne's teachings, deNormandie and the Instructive Nursing Association of Boston.

Obstetrics reached its full dignity as a special-

Dr. Sadler is Chief, Department of Obstetrics and Gynecology, Minneapolis General Hospital.

ty in the early twentieth century. Midwives did not give up their place in the field without a struggle.

In the sixteenth century, Dr. Wertt of Hamburg realized the study of the birth process should be at an actual labor. He disguised himself as a woman in order to be admitted to the lying-in-room and attended confinements in his district. Upon discovery of his masquerade, his punishment was swift. He was burned at the stake in 1522 as a lesson to watching physicians that midwifery was a woman's art. In our early colonial days, articles denouncing the fashion of having men midwives appeared in newspapers of the time.

Minnesota's obstetric progress during the century is highlighted by its contribution to medical education, lowering of maternal mortality, early entry into preventitive obstetric medicine by widespread prenatal care and by contributions to reduction of stillbirths and neonatal deaths.

Medical Education

As a result of the Flexner report in 1910, Dr. Vincent, president of the University, reorganized the faculty of the Medical School in 1913. Dr. J. C. Litzenberg was given the chair of Obstetrics and Gynecology. He retired in 1938, becoming emeritus professor. Credit is due his predecessors, Doctors Parks Ritchie and Ames. The Litzenberg story has been told many times. The contributions of this lovable, remarkable man to Minnesota's obstetrical education are monumental. In any field of endeavor, competent, trained personnel is a prime requisite. This he realized. He gave his teaching life to the problem of turning out excellently trained men. No man was prouder than he of the accomplishments of "his boys."

He was influential in establishing the requirement of serving an internship before qualification for the degree of M.D. He played a large part in the development at the University of the system of teaching fellowships for graduate students, leading to an advanced degree of Ph.D. This was a unique innovation in medical graduate study, as was the establishment of the Center for Continuation Study. At the latter, refresher courses are offered several times yearly for obstetricians and general practitioners.

Dr. Litzenberg was a founder and influential in organization of the American Board of Obstetrics and Gynecology in 1930. The high standards for becoming a diplomate of this Board has produced better qualified specialists. Diplomates by precept and example exert a strong influence on the instruction of thousands of medical students, interns, and residents.

Dr. Litzenberg's influence in teaching sound obstetrics grew beyond the boundaries of our state. He became a national figure in his field. He was succeeded in 1938 by Dr. John L. McKelvey, who with his staff, has made a long list of scientific contributions to obstetrics. Both of these great teachers have trained men who now head departments in other medical schools. Outstanding among these men are Drs. LeRoy A. Calkins, University of Kansas; Charles McLennan, Stanford University; Emil G. Holmstrom, University of Utah; and Curtis J. Lund, University of Louisiana.

The affiliation of the Mayo Foundation for Postgraduate Study with the University of Minnesota has resulted in numerous contributions to obstetrical progress, under the former department head, Dr. Robert Mussey, and the present head, Dr. L. M. Randall.

Maternal Mortality

In 1913 the Maternal Mortality rate in Minnesota was approximately seven per 1,000 live births, one of the lowest in the country. In 1938, the year Dr. Litzenberg retired, the rate was the lowest of any state in the union. Maternal deaths have continued to decline in Minnesota. In 1947, the death rate was 0.6 per 1,000 live births, an almost irreducible minimum.

The decline in maternal mortality in the United States has been general since 1930. Many factors have entered into this. An idea developed in Philadelphia by Phillip F. Williams in the early 1930's, adopted in Minnesota and elsewhere, has contributed much to this decline. This was the organization of Maternal Mortality Committees. The Minnesota Obstetrical and Gynecological Society sponsored the idea and our Maternal Mortality Committee is conducted under the auspices of the Minnesota State Medical Association and the University of Minnesota. Maternal deaths are analyzed as to their preventability. This alerts specialists and general practitioners alike as to whether faulty obstetrics has been involved.

Preventitive Obstetric Medicine

Today, as always, the three great killers and cripplers in obstetrics are: hemorrhage, puerperal infection, and the toxemias. These complications account for 90 per cent of all maternal deaths. Availability of blood from blood banks, chemotherapeutic and antibiotic agents and prenatal care have reduced markedly the deaths from this triad of killers.

Dr. Fred L. Adair, a graduate of Minnesota and associate professor on Dr. Litzenberg's staff, later became professor and head of the Department of Obstetrics and Gynecology at the University of Chicago. He headed the American Committee on Maternal Welfare from its inception. This committee has held four large congresses attended by some 5,000 physicians, nurses, public health workers, and others interested in the field. Among Dr. Adair's many contributions to obstetric progress while at the University of Minnesota was the impetus he gave to the development of prenatal clinics and proper prenatal care.

Many other agencies took part in placing Minnesota early in this field. The activities of the State Health Department, City Health Departments, Visiting Nurses Associations, Infant Welfare Societies, and Public Health Nurses played a large role in bettering maternal and infant welfare.

Reduction of Stillbirths and Neonatal Deaths

One function of the obstetrician is to insure a healthy child. There is a twilight zone between the birth of the child where his responsibility ends and the pediatrician's begins. Stillbirths and neonatal mortality rates from all causes, as well as from premature births (greatest neonatal death factor), have been declining in Minnesota and elsewhere the past fifteen years. Recently the curve has leveled off. Further reduction must be made in this area.

In 1951, a Neonatal Mortality Committee was established. A pilot study is now being made in Hennepin County under auspices of the County Medical Society. Plans for extending such studies to Ramsey, St. Louis and other counties are envisaged. Such plans are waiting results from the pilot study in our largest metropolitan center.

That there is urgent need for progress is evidenced by the fact that there are 150,000 infant deaths yearly in the United States associated with childbirth. As many as 1,874 infants died in 1950 in Minnesota. Three-fourths of these deaths occurred within the first thirty days of life. In the present state of our knowledge, many of these deaths are considered non-preventable. Much can, must and will be done to salvage this infant wastage. This also applies to the wasteage each year in the nation of an estimated 300,000 spontaneous abortions.

Conclusion

It may be said, it seems, without appearing chauvinistic, that Minnesota can take justifiable pride in its century of obstetric progress. Many challenges lie ahead. From our past history, we may be convinced that future progress in the field will find Minnesota playing its proper rôle.

MEDICAL JOURNALISM IN MINNESOTA

(Continued from Page 348)

others concerned in organizational affairs. For the past five years I have been a member of the Advisory Committee of the State Journal Advertising Bureau (formerly the Co-operative Medical Advertising Bureau) which has been providing an increasing amount of advertisements for the member journals of the Bureau. Last year the Bureau remitted to the member journals advertisements netting over $600,000.

I wish to take this occasion to express my appreciation of the support of the associate editors and the Editing and Publishing Committees during these many years. While editing a journal requires hard work at times, it possesses a certain fascination and a reward in itself for having stimulated one's best efforts.

NEUROLOGIC AND PSYCHIATRIC TRENDS IN MINNESOTA

A. B. BAKER, M.D., B. C. SCHIELE, M.D., D. W. HASTINGS, M.D. and
R. A. JENSEN, M.D.
Minneapolis, Minnesota

THE NATURE of mental illness is such that individual families are seldom able to provide private care for mentally ill relatives. Hence, the establishment of public facilities has been and is regarded as a proper responsibility of the state. By 1862, Minnesota began to assume responsibility for the care of its own mentally ill. At first, these patients were boarded in the hospitals of neighboring states, but by 1866 the state had been able to establish temporary facilities at St. Peter, Minnesota. The first permanent building was partly completed and began to be used in 1870. Five years later, 530 patients were being cared for. Many of these had to be housed in temporary buildings as the legislative grant had not permitted the building of a sufficiently large, permanent structure. Even then, a number of unimproved patients had to be sent back to home communities in order to make room for new cases. The demand upon the existing facilities was so great that, for a time at least, each county was required to take back one partially recovered or chronic case for each new patient admitted.

These early struggles to provide adequate facilities for the ever-growing population of the mentally ill in Minnesota in large measure composed the early history of psychiatry in the state. For many years, the only physicians practicing psychiatry in Minnesota were those men who were on the staffs of the mental hospitals. Gradually, new hospitals were built and institutions were established for the care of the various types of incapacitated persons: the inebriate, the epileptic, the mentally deficient, the psychotic, and the criminally insane. Today, Minnesota has nine separate institutions with a total bed capacity of 9,546.

Throughout the years, the provision of adequate care for these sick people has constituted a serious problem and a significant drain upon the financial resources of the state. Although there have been many significant advances, the present-day problems of overcrowding, inability to obtain adequate staff, long waiting lists, and similar problems have been with us since 1866. Historically, the recent emphasis upon the mental health program of Minnesota in many ways is an interesting repetition of occurrences of the past. Then, as now, the struggle between practical economy and the desire for better facilities has led to action on the part of citizens' groups. Several "commissions of eminent medical men" have served in advisory capacities to the governors of the state. Throughout the years, the legislature has been besieged with pleas for furnishing the financial means for better care of the mentally ill. As early as 1880, petitions were made for increasing the ratio of attendants to patients, for the better selection and training of attendants, and for the abolition of restraints.

The course of neuropsychiatry in Minnesota has been molded in large part by a number of eminent medical men. In the late 1800's their industry and scholarly contributions did much to raise the level of medical practice, particularly in this specialty. The names of Drs. A. A. Sweeney, C. E. Riggs, W. A. Jones, and A. Hamilton are among those who were nationally prominent, who were studious investigators, skillful writers and teachers. These men had broad medical and civic interests.

Prior to the establishment of formal training programs in neurology and psychiatry that we have today, private practitioners generally went into the neuropsychiatric field after a period of work in a mental hospital or after being associated with a man specializing in the field. The emphasis tended to be largely on neurology and the care of the frankly psychotic. This was true on a national as well as on a local level.

In recent years, men with more formal training, particularly in the separate fields of psychiatry and neurology, began private practice in Minnesota. Since World War II, there has not only been a large increase in the number of neurologists and psychiatrists in the state, there have also appeared those who have limited themselves to the private practice of office psychotherapy and several have limited themselves to psychoanalysis. As a national phenomenon occurring during and immediately after World War II (and in some centers a number of years earlier), came a separation of the former specialty of "neuropsychiatry" into its two components of neurology and psychiatry. The fields of knowledge in each specialty have become so great that it was evident that each deserved the rating of a separate specialty. This was reflected in numerous ways: at the national level, by the reorganization of the examining body into that of the American Board of Psychiatry and Neurology with separate periods of residency training required for qualification in each specialty; at the state level, by the reorganization of the University of Minnesota Medical School Department of Neuropsychiatry into the two divisions of psychiatry and neurology with separate clinical services and teaching schedules. The two divisions, however, are in the same department and enjoy a mutually beneficial relationship. A similar division of professional labor took place in the structure of the Mayo Clinic. It is evident that there are large areas of overlap between the two specialties (for example, in the organic psychoses, in basic research problems, and so forth); but in general the two fields, in more recent years, have come to involve different types of training and different clinical techniques.

Since its early years, the Medical School has always had a division or department of nervous and mental diseases. At first its staff was made up entirely of part-time physicians. The first full-time staff appointment began with Dr. J. C. McKinley in 1921. During most of its existence, neuropsychiatry at the University had been heavily oriented toward organic neurology. The psychiatry that was taught was largely limited to the gross psychoses and was largely descriptive in character. This was in keeping with the national trends of the time.

For some years there had been recognized the need for the establishment of a Minnesota psychopathic hospital to function as a teaching and research center. After much controversy and many delays, a 37-bed psychiatric unit was opened at the University in 1937. Along with the increase in the size of the neurologic service and the establishment of an excellent neuropathologic laboratory, the University became much better equipped to teach a well rounded program in both neurology and psychiatry. It was not, however, until after World War II that the staff expanded sufficiently to allow an adequate teaching of modern psychodynamic psychiatry. Perhaps the most important change was the introduction of a comprehensive orientation of medical psychology throughout the four years of medical school.

Interest in developing a child guidance service in the Twin Cities resulted in the establishment of a Demonstration Clinic in November, 1923, which was located at the University of Minnesota. This one-year demonstration led to the establishment of three services: (1) a Child Guidance Clinic in Minneapolis under the Board of Education, (2) one in Saint Paul under the sponsorship of the Amherst H. Wilder Charities, and (3) one at the University of Minnesota to serve the state. The last service was discontinued in June, 1925 due to the lack of legislative support. However, this two-year program influenced the development of the Duluth Mental Hygiene Clinic and later paved the way for the development of comprehensive psychiatric services to children at the University of Minnesota Medical School. In 1938, the Psychiatric Clinic for Children was established at the University Hospitals and Medical School, supported initially by the Commonwealth Fund and the Stevens Avenue Home for Aged Women and Children. After a five-year demonstration period, the University gradually assumed full support of this important service as an integral part of the Medical School and University Hospitals to culminate in the establishment of an in-patient psychiatric service to children in 1952. In addition to the increased service to children and their families, this development has contributed to the psychiatric and pediatric teaching program of the Medical School.

Other psychiatric services to children include the developments at the Mayo Clinic in the middle forties and the establishment of the Washburn Memorial Clinic in Minneapolis in 1950.

Another national trend has seen the utilization of the ancillary fields of clinical psychology and psychiatric social work in both neurology and psychiatry. In 1951, the University of Minnesota Department of Psychiatry and Neurology established a third branch, the Division of Clinical Psychology. This permitted a more effective use of the techniques of psychology, not only in clinical areas but particularly in research activities.

If one were to attempt to name the most significant historical change in psychiatry, it would probably be the fact that the field of psychiatry has made the transition from its isolated position in mental hospitals to joining forces with the entire family of medicine. This has been reflected in many ways in both clinical practice and in teaching procedures. The years since World War II, at both a national and state level, have seen a marked interest on the part of both psychiatrists and non-psychiatrists in the orientation, for example, of the general physician toward those techniques of psychiatry which are useful in his everyday office practice. On his part, the psychiatrist has interested himself much more extensively in the everyday problems of medicine; for example those associated with the multitude of illnesses termed psychosomatic in nature. On his part, the internist, the general physician, and the surgeon have become interested in the psychological aspects of the illnesses which patients bring to them; and in turn these men have made real contributions to the field of psychiatry. Over the last quarter of a century, the field of psychiatry has found itself in a state of flux, this transition from the mental hospital to the general practice of medicine being one of the most significant. Another development which is just in its beginning, from the point of view of any large scale endeavor, is the marked interest in research and investigation with regard to psychological illnesses. It is highly likely that this development in the years ahead will spell one of the major contributions toward the more adequate understanding of these baffling illnesses.

During this same period, neurology has also shown a very definite change of emphasis from that of diagnosis and the care of the hopeless and chronically disabled neurologic patient to a more dynamic interest in total treatment and the care of all problems related to the nervous system, both acute and chronic. Diagnosis in the field of neurology has been expanded by the introduction of such procedures as air encephalogram, electroencephalogram, and more recently arteriogram. At the same time, a large number of newer therapies have become available for the treatment of many of the neurologic disorders such as the convulsive disorders, myasthenia gravis, neurosyphilis, subacute combined degeneration, parkinsonism, etc. This change in the emphasis of neurologic practice has been apparent in the increasing number of physicians who are taking specialty training in neurology as well as the increasing awareness of the practicing physician of neurologic problems. Research in the field of neurology has greatly expanded at the University of Minnesota and has seen a wide range of interests from the care of bulbar poliomyelitis to a new interest in the chemistry of the nervous system.

A HUNDRED YEARS OF PROGRESS IN THE THERAPY OF URINARY INFECTION

Comment

It is never safe to be a prophet in a scene which is changing almost from day to day, as it is in the specialty of urology. Yet prognostication in any field of human endeavor is always inviting, sometimes fatally so. In the foregoing text an attempt has been made to point out very briefly the vast differences between the practice of urology a century ago and the practice of urology today. Some of the practitioners who helped to found the Minnesota State Medical Association learned what they knew about urology empirically; others had the benefits of the best formal training of the day. Their knowledge, in any case, was infinitesimal, and much of it was downright erroneous, in comparison with that possessed by the urologist of today. A hundred years from now, an overly hopeful seer might say, there might even be no urologists, simply because there will be no more worlds for the urologist to conquer.

RAPID FROZEN SECTIONS—THEIR VALUE IN DIAGNOSIS

MALCOLM B. DOCKERTY, M.D.
Rochester, Minnesota

"The paraffin sections will be rushed through and we should have the diagnosis by Tuesday." So familiar has become this pathologic proclamation that, even in this age of turbojets, clinicians and surgeons are prone to accept its implied policy of delay in terms of a modern miracle of speed. Yet, it is a fact that, with the exception of certain calcified elements such as bone and teeth, no solid tissue exists that cannot be readied for microscopic examination within minutes after its removal from the body. Pathologists are familiarizing themselves with certain fast-acting vital stains that impart to tissues a range of cytologic detail which heretofore has been impossible to obtain from similar tissues fixed for a matter of days and stained by time-honored techniques.

The present communication is intended to acquaint both general practitioner and surgeon with the advantages of exploring with their respective pathologists the possibilities offered by use of fresh frozen sections as a means of rapid diagnosis.

1. Is a specimen for biopsy representative? Even poorly prepared "slabs" of tissue are thin enough to allow for a decision as to whether the tissue is alive or dead. Nonviable tissue rarely discloses useful information after treatment by any method of fixation and sectioning and its identification as such demands further sampling by biopsy.

2. Has surgical excision encompassed the entire lesion? The answer to this vital question far too often has been disclosed by studies of "pickled" specimens. For benefits that rightly should accrue to the patient, determination of the limits of lesions, particularly new growths, should be done during operation. Nobody likes to sew "cancer to cancer," even for cosmetic results.

3. Is a malignant lesion primary or metastatic? Recently, I was consulted about a slide prepared from an ovarian tumor that had been removed from a young woman. The presence of unmistakable signet-ring cells made almost certain a diagnosis of gastric carcinoma, which later was established by gastric roentgenograms. The correct diagnosis could have been made by means of fresh frozen sections at laparotomy.

4. Is a lesion benign or malignant? The answer to this question often indicates the type of operation to be done. In more than 95 per cent of cases, this problem is settled immediately at the freezing microtome. In my opinion, malignant changes in such locations as the uterine cervix or fundus, the bladder, the breast, the thyroid, the brain and in bone—to list a few—are delineated just as clearly by the rapid freezing method as by routine paraffin techniques carried out several days later. When the lesion is a "debatable" one, it is always possible to withhold opinion and "stall for time with hematoxylin and eosin." Such lesions will frequently still be "debatable" after prolonged fixation, embedding and staining.

5. Is a lesion inflammatory or neoplastic? An excellent example of this diagnostic dilemma concerns the thickened pancreatic head in the patient who has obstructive jaundice. The issue can be resolved rapidly by use of the Silverman needle to secure deep cores of tissue. Microscopic examination of these fragments can be carried out by freezing almost as rapidly as the surgeon can remove them. Curettings from the interior of the common bile duct yield comparable information of a most useful nature to the surgeon who is con-

---

From the Division of Surgical Pathology, Mayo Clinic, Rochester, Minnesota.

templating performance of a Whipple operation or some other major procedure.

For the general practitioner, needle biopsy is coming into its own. Tissues so secured from the breast, prostate gland, thyroid, lymph nodes, spleen and liver all lend themselves to examination by the rapid freezing method. Consider the patient whose nodular liver possibly contains metastatic tumors. The clinician weighs the appreciable risk of exploratory laparotomy against the usefulness of information obtained thereby. However, with minimal risk, multiple sampling of these nodules can be done by means of the Silverman needle. Pathologic examination of these cores of tissue often settles a diagnosis that otherwise would require a week's hospitalization.

6. Finally, the method directs approaches to bacteriologic investigation. Many infections, particularly granulomas, require specific antibiotic therapy based on isolation of the causative organism. Use of fresh frozen sections may allow identification of the specific nature of these lesions; at least the method can suggest the necessity for special cultures of excised tissues. Paraffin blocks, on the other hand, make poor material for bacteriologic investigation.

These are but a few examples of the role of fresh frozen sections in diagnosis. For best results and to breed familiarity with the method, it should be employed routinely. Promotion of its use requires enthusiasm tempered with patience on the part of clinicians and surgeons, who must encourage in their colleague in the laboratory a sense of pride in his accomplishments in making correct diagnoses. They must not chide the pathologist for his reluctance to accept wholeheartedly what, at first, is to him an unfamiliar method for the examination of tissues. The pathologist, for his part, should recall that familiarity with the method breeds attempt.

* * *

This presentation, the fourth of a series of editorial reports designed to focus attention on aids to medical practice offered by the practitioner of laboratory medicine, outlines an important aspect of pathology that is tinged with the crimson of controversy among pathologists themselves. Although techniques of fresh frozen sections were first employed almost half a century ago, many freezing microtomes are gathering dust in long-forgotten corners of laboratory closets. Yet any method that, in the hands of a pathologist experienced in its use, can produce correct histologic diagnoses in more than 90 per cent of cases in a matter of a minute or two, deserves wider application than it is presently accorded. As Dr. Dockerty says, "Familiarity breeds attempt."

The Editorial Committee of the Minnesota Society of Clinical Pathologists welcomes ideas concerning this series of reports. Reprints of this article are available from either the author or the chairman of the committee.

DERMATOLOGY IN MINNESOTA

(Continued from Page 377)

gral part of Minnesota dermatology as well as a strong national influence.*

Much more of dermatologic interest could be recalled: the unique characteristics of some of the earlier practitioners, the many sincere friendships and the almost complete lack of jealousies and bitterness, changes in the character and the techniques of practice in this field, and the extension of adequate dermatologic care over all of Minnesota. In all these features the story of dermatology parallels that of other fields of medicine in Minnesota and need not be recounted here.

---

*The close personal friendship and high mutual regard of Dr. O'Leary and Dr. Michelson have done much to unify, develop and expand dermatology in this area and to stimulate those who have worked with them. In character and in ability, as teachers and as physicians, they are not outranked anywhere in America.—F.W.L.

President's Letter

FOR THE BENEFIT OF THE SICK

With this issue, we officially commemorate the completion of 100 years of organized medicine in Minnesota. Because of this, it is altogether fitting that we should take a long look, both forward and backward, in an effort to see where we've been travelling and where we are going.

In looking back, we should remember that in the year of the Minnesota State Medical Association's founding, 1853, physicians, except for limited knowledge, were not essentially different from those of today. That is, they were constantly learning new scientific facts, were meeting to discuss new ideas, theories and experiments—and always with the thought in mind—"for the benefit of the sick."

After 100 years of medical organization in the state, that same theme, one of the key phrases in the Hippocratic oath, permeates medical practice as a whole and becomes the dominate motivating factor in medical progress.

Through the trials of early organization in the Minnesota State Medical Association, the pioneer doctors of the state made rapid strides both in organizational work and in scientific knowledge. With the ravages of early disease in epidemic proportions, the Medical Association became instrumental in the establishment of a State Board of Health in 1872. Preventive medicine thus received impetus in the state.

In surgery, Minnesota was one of the pioneers. The introduction of anesthesia and methods of antisepsis were generally accepted in Minnesota well before 1890. Among the surgical "firsts" in the state was the first operation reported for removal of the gall bladder.

Association activities have increased and expanded greatly over the years. Public health education has been one of the most important, together with the fostering of ever higher standards for medical education. All these activities have been aimed at the goal "for the benefit of the sick." Medicine always has, and always will be. dedicated to that purpose.

In looking forward to the continuation and further expansion of these dedicated purposes, the medical profession of the state can be proud that Minnesota ranks high among other states in scientific, educational, social and moral progress.

And, although we are this year taking stock of what we, as a medical profession, have achieved, we cannot afford to look only backward. In spite of diversions, we must look forward to even finer improvements, and we must pledge ourselves in all sincerity to higher goals in better medical care for the benefit of the sick.

Orwood J Campbell

President, Minnesota State Medical Association

STATE MEDICAL ASSOCIATION CENTENARY

THE YEAR 1953 is the centenary of the founding of the Minnesota State Medical Association. It was on July 23, 1853 that a small group of physicians living in the Minnesota Territory met and established the Minnesota State Medical Society.

It is interesting to pause from time to time on the occasion of certain anniversaries to review changes that have taken place in the different phases of our manner of living. Even fifty years ago, within the memory of many of us, there were no automobiles, aeroplanes, movies, radios, television sets, skyscrapers—to mention the outstanding inventions which have modified our way of living. If we go back a hundred years, life was still more primitive for there were then no telephones nor railroads—in Minnesota, at least.

When it comes to the field of medicine, the advances during the past hundred years, and more particularly in the past fifty years, have been phenomenal. The seriousness of many diseases and their very existence in certain instances has been eliminated. Consider, for instance, diphtheria, appendicitis, typhoid fever, pneumonia, mastoiditis, cholera infantum, diabetes mellitus, pernicious anemia. The progress made in medicine and public health has been reflected in the almost unbelievable rise in life expectancy and the improvement in health during the last century.

In an effort to call attention to the progress made in the medical field since our State Medical Association was founded a hundred years ago, this issue of the journal is being devoted to articles contributed by members in the various fields of medicine. They should prove to be interesting reading.

The annual meeting of the Minnesota State Medical Association will take cognizance of its hundredth birthday. An exhibit will display a typical doctor's office 100 years ago. An unusual number of out-of-state guests, including Sir Alexander Fleming and Dr. Richard R. Trail, both of London, will take part in the program.

The annual banquet will be held on Tuesday evening at the Saint Paul Hotel and will be addressed by Dr. O. J. Campbell, president of the State Association and Dr. Louis H. Bauer, president of the American Medical Association. The meeting will be featured by the popular round table discussions and symposia on Gastrointestinal Diseases, Fractures, Marginal Neuroses, Chest Diseases and Eye and Ear Diseases.

This year's meeting promises to be one of the largest in point of attendance. Fewer addresses will be given in deference to the longer time allotted to the visitors.

Attention is called to the program of the meeting which appears in this issue.

Remember the date—May 18-20; and the place—Saint Paul.

REORGANIZATION, WITH RESERVATIONS

A DRAMATIC and historic meeting of the AMA House of Delegates, which was attended and addressed by President Eisenhower, Federal Security Administrator, Mrs. Oveta Culp Hobby, Senator Robert Taft and Minnesota's Congressman Walter Judd, was held in the Statler Hotel, Washington, D. C., on March 14 for the single purpose of considering a reorganization of the Federal Security Agency. The reorganization plan, as submitted to Congress, includes renaming the department "Health, Education and Social Welfare," to be headed by Mrs. Hobby, with the probability of her becoming a cabinet member.

In 1884, the American Medical Association presented a resolution to the national government asking for a department of health, with a doctor of medicine in charge as a cabinet member. In the succeeding sixty-nine years, no such action has been consummated.

The reorganization plan for the new department divides the previous agency into health, education and social welfare. Immediately under the department head, according to the administration spokesman, there will be a doctor of medicine in charge of the division of health. To his attention will come all matters of the entire department relating to health, and out of some more than eighty different agencies now handling health matters, the affairs of almost half of these will come over the desk of the medical director.

The arguments presented for the present reorganization plan were that it is a definite step toward placing health matters in the hands of a medical man who has not been associated in the past as a career man with the government's contacts with health matters. The reorganization plan specifies that qualification.

In the administration's plan of decentralization in Washington and replacement of problems, as far as possible, in state and local hands, this reorganized department will probably have coming under its direction an increasing number of agencies of the type where the national administration desires to return duties to the state and local levels. England has a Minister of Health of cabinet rank and of considerable central authority, which probably made it easier for England to convert to its present system of state medicine. This was presented at the meeting as an argument against having a medical department of cabinet rank.

Besides the speakers first mentioned, President Bauer of the American Medical Association and Chairman Murray of the AMA's Board of Trustees also discussed the reorganization.

The House of Delegates adopted a resolution prepared by the Board of Trustees endorsing the reorganization plan, but with a preamble or reservation that in the past the profession had felt that health activities should have cabinet rank in its own right and the American Medical Association in the future would feel at liberty at any time to criticize or offer suggestions or amendments to the reorganized department.

One immediate value of the reorganization plan is that the department will be able to place in charge of the divisions, people in sympathy with free enterprise and national decentralization of the agencies involved. Without the reorganization, department heads would be those who had been blanketed into the Civil Service and members appointed under the past administrations, and hence probably not sympathetic to the new viewpoint.

AMERICAN MEDICAL EDUCATIONAL FUND DRIVE

As STATE and Sixth Councilor District Chairman of the American Medical Educational Fund Drive I would like to bring to your attention the pertinent details relating to this extremely important and worthwhile project sponsored by the American Medical Association.

As State Chairman of this educational endeavor, I met with the AMA committee in Chicago on January 25, 1953. Those in attendance were given a comprehensive outline of the aims and objectives of the Medical Educational Fund. The success of this project has broad and far-reaching implications which could well determine the future policies of our medical schools as well as indicate to the American people and our government how far we as doctors are willing to go in defense of the private practice of medicine in this country. We are fortunate in having the enthusiastic support and financial backing of many private industrial enterprises.

I should like to say here that after making a study of the AMEF, I believe it is a worthy cause. The medical schools of our country are the foundation of America's health. They turn out the doctors, medical scientists and researchers essential to economic and social progress. They train the medical manpower needed to staff our hospitals, health programs and the expanding practice of industrial medicine. To lower the standards of teaching or to reduce the medical manpower would be disastrous.

Careful and exhaustive studies indicate that our seventy-nine approved medical schools will require additional annual subsidies amounting to approximately ten million dollars. The funds must come either from government or private sources. It is obvious from the report submitted by the committee sounding out American business, that private industry prefers the latter. Both business and industry have already subscribed generously to this medical educational fund. However, many more thousands of doctors of medicine should respond in support and defense of their chosen profession.

Perhaps you are now asking, where does the need for such a large annual fund lie? Medical training is by far the most expensive field of education. The rapid increases in costs have been staggering. The average cost of training a doctor has doubled in twenty years to $10,000. Tuition fees, raised 165 per cent since 1940, pay only one-fifth of this cost. Other factors contributing to the increased cost are: (1) lengthy period of training, (2) costly laboratory facilities, (3) high ratio of teachers to students, (4) complicated training techniques arising from recent scientific advances. Why doesn't each state-supported school increase its budget requests to cover its needs? The answer to this is the same as it always has been. Drastic cuts in budgets are set up for specific uses. Herein lies the difficulty—lack of unrestricted funds. Unrestricted funds can be used to augment the salaries of worthy underpaid faculty members, provide laboratory facilities, improved and expanded out-patient services for medical students, et cetera.

How are we, as doctors in active practice, to benefit?

The medical schools of our nation are graduating over 6,000 new doctors every year—doctors with new knowledge, new techniques, and vast new resources.

It should be clear to every physician that if medical schools continue to operate without proper finances, it will seriously damage the teaching system and ultimately lower the standard of medical practice in the United States. American physicians cannot afford to permit the weakening of their professional standards which are the backbone of a nation that enjoys the highest health levels in the world today, nor can they permit the creeping paralysis of government control to envelope their schools and ultimately dictate the standards of medical practice.

Give serious thought to this venture, in which each one of us must play a part, whether we give generously according to our means, or not at all. Your contribution can be designated to the school of your choice, in which instance every dime of it will be channelled back to that school by the National Fund. Funds given directly to any medical school do not become a part of the National Fund and cannot therefore reflect professional support, which in turn would have a bearing upon contingent donations from business and industry. Undesignated gifts will be prorated among the seventy-nine medical schools.

Bear in mind, contributions to the AMEF are tax exempt. Therefore, you can afford to be generous by allowing yourself a reduction in your taxes at the same time you are supporting a mighty worthy cause.

H. E. Drill, M.D., *Chairman Minnesota Division and Sixth Councilor District of American Medical Association Educational Fund Drive.*

FALSE PROPAGANDA

ONE of the most inexcusable examples of propaganda in its worst form was a movie which appeared over twelve television channels in California a few months back. The broadcast was sponsored by the International Association of Machinists. Just why this union should spend its money to mislead the public, we do not know.

The playlet, entitled "Without Fear," is a story based on statements assumed to be true that 325,000 Americans die annually because only one out of five can afford the costs of serious illness; that America needs three times as many physicians as we have; that America has only half the hospital beds it needs, et cetera.

A story is dramatized in which a parent of modest means calls a physician for a sick baby. One physician can't come, another won't, another demands preliminary assurance of an unreasonable fee ($15). The baby dies; care came too late after the distraught mother takes it to the hospital where she learns that the baby is the victim of neglect. The story brings in an overworked physician who just can't meet the demands on his time and energy.

The movie then goes on to explain that the shortage of physicians is due to the AMA which refuses to admit a shortage of physicians, for members find it to their advantage for a shortage to exist. Then it is told that if the government only ran the medical care of the people and that if the bills in Congress to accomplish this were only passed instead of being blocked by AMA lobbyists, all would be well.

No mention is made of the possibility that there are plenty of physicians in relation to the population; that the output of physicians is increasing at a faster rate than the general population; that the AMA is not responsible for the production of physicians by the medical schools; that the overall cost of medical care would probably be increased tremendously and the service would be of inferior quality under government control; that the experience with socialism in New Zealand, Australia and Great Britain has resulted in a reversal of public opinion.

This movie, "Without Fear," is a convincing proof that efforts to socialize the medical profession and the country have not been abandoned. The price of liberty is eternal vigilance.

GAMMA GLOBULIN FOR MEASLES AND HEPATITIS

Recently, the National Foundation for Infantile Paralysis completed negotiations for the purchase of the present inventory of certain processors of commercial gamma globulin as well as the future production by these same producers. In agreement with the American National Red Cross all gamma globulin processed from Red Cross donated blood, as well as the commercially produced gamma globulin purchased by the National Foundation, has been placed under control of the Office of Defense Mobilization. The National Foundation does not have in its possession or control any supply of the blood fraction.

It has been agreed by all parties concerned that gamma globulin will be available for measles prophylaxis and for use by physicians in the treatment of infectious hepatitis, irrespective of the resulting limitation of gamma globulin available for use in poliomyelitis epidemics.

The Office of Defense Mobilization will allocate the available gamma globulin through State and Territorial Health Officers for use in measles and infectious hepatitis, and will make additional distribution for the purpose of controlling poliomyelitis.

Physicians who are unable to purchase gamma globulin through their regular drug supply channels are advised to request supplies from their local or state health departments. There will be no charge for this gamma globulin, since the Red Cross has already paid for the processing and packaging of the material, and the National Foundation for Infantile Paralysis, through its arrangement with the commercial processors, has purchased the commercial supply at the same rate as that currently supplied defense agencies under governmental contract.

The National Foundation does not have gamma globulin available for distribution, nor will it determine how available supplies shall be used. That is the function of the Office of Defense Mobilization.

Since it has been obvious for some year and a half that gamma globulin would be in short supply, the above plan was agreed upon by all interested agencies, governmental, private and public, to avoid wasteful use of gamma globulin.—*National Foundation for Infantile Paralysis Release March 13, 1953.*

Only by a biopsy competently interpreted can the diagnosis of malignant lymphoma be anything more than a guess.

THE PROBLEMS OF TUBERCULOSIS CONTROL

Recent advances in the treatment of tuberculosis have raised for new consideration the question of proper balance among the procedures now employed in control of this disease.

During the period from 1900 to 1925 there was a rapid advance in diagnosis due to improved roentgenological techniques and bacteriological methods. Treatment, which, before 1925, had emphasized fresh air, proper food, and rest, acquired pneumothorax and collapse therapy. The second quarter century was one of accelerated development of case finding, hospitalization for purposes of isolation and care, a variety of measures for prevention, and finally social assistance for patients and their families.

This brings us to the opening of the third quarter. Optimists, watching the declining mortality from tuberculosis, predict its virtual eradication in the United States. Conservatives are concerned with the continuing high prevalence of known cases. In any event there is immediate urgency in co-ordinating and integrating the present measures. The decision as to the wisdom of a change or modification of our efforts will depend on our evaluation of the success of present measures of which a brief summary is presented for consideration.

Case Finding: There are three major methods of case finding today. The first is the discovery of cases by physicians engaged in private practice. Private practitioners are the ones most likely to have first knowledge of cases that have progressed to actual symptoms. The second is search for cases on a contact basis. This is essentially clinic practice and rests on the principle that one case of the disease comes from another. The third, mass roentgenographic surveys of large segments of the population, is organized on the sound theory that a large enough relatively inexpensive net will gather in most of the unknown cases.

Medical Treatment: Medical treatment has passed through the stages of primary emphasis on hygienic care, collapse therapy, surgical measures, and drug treatment, to the present period of a combination of chemotherapy and surgical practice, and effective rehabilitation. The cardinal requirement is the hospital bed for tuberculosis, and it is indeed the crux of present-day problems.

Prevention: Proper treatment is itself a large part of prevention because it removes sources of contagian from susceptible persons. In the best organized communities today, hospital treatment of the patient is supplemented by supervision and education of family at home. To this is added in small segments of our population, BCG vaccination.

Social Assistance: This varies all the way from abolition of the means test as a requirement for hospital admission to direct financial grants to a patient's family during the period of non-employment of the patient.

All social assistance programs include rehabilitation of hospital patients. Experience has shown that the patient's morale and faithfulness in taking treatment depend in large part on the support given his family in his absence.

Mortality: Tuberculosis mortality in the United States declined 90 per cent from 1900 to 1950. The mortality in 1950 was only half that of 1945. Tentative figures indicate that the death rate for 1951 was 20 per 100,000 population. A breakdown by race, sex, and age shows that the mortality rate in non-white persons is about three times that in white persons, and that more than half of all deaths from tuberculosis now occur after the age of forty-five years. The greatest number of deaths from tuberculosis today occurs in old white males.

Prevalence: It is agreed that the *known* prevalence of the disease has declined little in the last twenty years. Failure to decline is due, in part, to improved case-finding procedures and increased longevity of patients. The total number of cases of active disease in the United States is 400,000, approximately 250,000 of which are known to health departments.

Incidence: The average annual incidence of new cases reported in the whole country has been about 120,000 in recent years. The figure was 118,000 in 1951, a drop of 19,000 cases from the 137,000 in 1948. This drop is probably significant.

Hospitalization: Hospitalization is recognized as the core of tuberculosis control. Until recently the minimum number of beds required for adequate control was judged to be two and a half times the number of deaths from tuberculosis annually in the community. Three beds per annual death were recommended. Many communities are still far from meeting the minimum standard but some substantially exceed it. At present in the United States approximately 102,000 beds are set aside specifically for tuberculosis. The standards in the future may be based on known prevalence rather than deaths.

Cost of Tuberculosis Program: The annual total cost of tuberculosis control in the United States is calculated as $350,000,000, exclusive of construction expense and the cost of training personnel. This includes the sums spent on hospitalization, which is figured at $200,000,000 a year, or more than half the cost of the whole tuberculosis program. Finally, we may note that the average cost of one case of tuberculosis is about $15,000.

With this background, what is the best plan for tuberculosis control in the future? Two courses are obviously open, viz., (1) to keep on as we are doing, improving procedures whenever possible, and (2) to revise the program by introduction of some new principle. We may rest reasonably well assured that in time the first of these procedures will relegate tuberculosis to a minor position among diseases, though only at great cost. It will mean a steady increase in measures for case finding, more hospital beds and larger sums for rehabilitation. If inflation continues, the dollar cost will be magnified. Even so, the price might be small in comparison with allowing tuberculosis to persist in our population.

A better course cannot be outlined now, but some elements of the program merit careful scrutiny. The hospital program costs $200,000,000 and this will probably be increased. The internist may inquire if full advantage is being taken of the powerful force of private practice in supplementing hospital care. Hospitalization in effect does not provide for all the tuberculous patients in need of care, and many hospitals have waiting lists. The latest and best methods of surgery and chemotherapy have not shortened but freqeuntly have lengthened the optimum period of hospital stay.

Herein, however, lies one possible change in which the private practitioner is concerned. After completion of the necessary active therapy and the accompanying indoctrination in personal care, could not the time-consuming final steps in the cure, particularly the essential long continued chemotherapy, be carried out at home, with safety and success, by private physicians?

This suggestion may have merit. Much depends on improved understanding of tuberculosis by physicians in general practice and on the character of the homes in which treatment is given. Tuberculosis is most prevalent today in the economically underprivileged. The problem is not purely medical, but is inextricably bound up with social issues. There is reason to hope that the standard of living will continue to rise. In the meantime, more intelligent application of the skills of practicing internists may solve part of the problem. Competent home after-care of tuberculous patients who have had a satisfactory course of institutional treatment, is one possible way of saving hospital time and relieving bed shortages.—By Esmond R. Long, M.D., *Annals of Internal Medicine*, November, 1952.

WANTED—Millions of Miracle Makers!

Over 60 million Americans can be miracle makers. You are probably one of them. Any person from 21 to 59 who is in good health and weighs 110 pounds or more is eligible.

The miracle you can perform is saving human life. Yes, you can really help save precious lives. And it is important that you do it right now!

Although the miracle of saving human life challenges the imagination, you can do it with a little of your blood. In less than an hour you can simply and painlessly donate a pint of your blood to help someone live.

The National Blood Program is calling on you to help in this miracle making business so that no one here at home or our men fighting in Korea need die for want of this vital substance.

You are needed at your local Blood Donor Center now. Call your local Red Cross Chapter to schedule your donation today.

Medical Economics

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

FACILITIES INCREASE FOR RURAL MEDICAL CARE

The eighth National Conference on Rural Health, held in Roanoke, Virginia, on February 27 and 28, was told that medical care facilities in rural areas are increasing rapidly through the cooperative, voluntary efforts of medical, farm and community groups.

The report was made by Dr. Louis H. Bauer, president of the American Medical Association, who told delegates, "All groups are cooperating in an effort to bring the highest standards of medical care to rural areas. No one organization can do the job by itself. It requires community effort."

States Past Difficulties

Dr. Bauer outlined past difficulties which rural communities encountered in obtaining physicians for their areas. He said:

> "One of the difficulties in the past has been the developing of some means to attract physicians to those regions lacking them. A physician who has spent 8 to 13 years of his life in being trained to practice modern medicine is not willing to settle in an area where there are no facilities for practicing such a type of medicine. Increasing the number of physicians will not do it, as they would still tend to congregate in cities."

Dr. Bauer pointed out that in some states, the problem has been solved by the community, which provides medical facilities and then permits the physician to rent those facilities or to buy them through gradual payments. "Where this has been done, physicians have been obtained," he stated. He noted, too, that in these days of good roads and automobiles a physician can cover a wider territory than before, and is able to take care of more people. He concluded that, "every community does not need a hospital so long as one is available within a reasonable distance and good roads lead to it."

No Santa Claus Program

The solution to many of the rural health problems is being found without the aid of statism theories, reported Dr. F. S. Crockett, chairman of the American Medical Association's Council on Rural Health.

Dr. Crockett said that in the planning for adequate medical care in small communities, one of the uppermost points has been that "there was to be no Santa Claus in the picture." He noted that much group strength has been obtained through the establishment of rural health councils, made up of all facets of community life, without extra Santa Claus aid from governmental agencies. "These councils," he said, "in many instances have brought about the elimination of health hazards and have taught simple health rules to improve conditions."

Since 1946, Dr. Crockett stated, many doctors have settled in villages, and he added that, "it is in communities on the lower economic income level that the greatest challenge exists. Places with poor schools, churches, roads, homes and farms go hand in hand with inadequate medical care."

Health Insurance Gains

The vice chairman of the AMA's Council on Rural Health, Dr. Carll S. Mundy, who told the delegates that voluntary group health and accident insurance coverage of farmers and their families, as an economical means for them to meet medical care costs, is on the increase. He noted that successful groups have been formed within farm organizations, among church members and among depositors of rural banks. In contrasting procedure of farm and city health insurance groups, Dr. Mundy stated: "Since payroll deduction is impossible for farm families, some other satisfactory and economical arrangement must be made to collect and forward premiums for the group."

The meeting drew more than 600 representatives of medical, agricultural, university extension services and other groups wth a combined membership of several millions. Forty-two states and the District of Columbia were represented at the conference.

The delegates were informed of many of the reasons why rural areas seemed to lack physicians. Dr. Paul D. Sanders, editor of the *Southern Planter,* blamed medical care problems in the rural areas of the South on the advantages of larger cities which draw doctors, dentists and nurses along with other segments of the rural population. He felt that another factor has been the backwardness of the South in modernizing its farming activities.

Local Examples Cited

Many speakers told of how communities had worked together to make their area attractive to a new doctor. One cited a small town whose residents organized, and with the help of the local farm organization, the county medical society and the state council on health and medical care, interested a young doctor in starting his practice there. They provided him with a building for a clinic and a place to live. Today, the clinic serves weekly from 250 to 300 patients from a widespread area. Another Southern community passed three bond issues to obtain a 55-bed hospital.

The theme of the meeting, "Widening the Highways to Health," was presented to the delegates by speakers from all phases of medical and rural life.

COMMISSION FORMED TO STUDY TAXES, SOCIAL SECURITY

A newly formed federal commission to study taxes and social security will begin work at once, to complete the study in one year. The commission, formed at the suggestion of President Eisenhower, is composed of Congressional, federal and state officials and will scrutinize federal-state relations in the fields of taxes and health and social security, and is authorized to recommend legislation.

Membership will include representatives named by the President, plus others designated by Congress and by the State Governors' Conference.

The commission originated at a White House meeting in February which was attended by representatives of the governors, Congress and the executive branch. President Eisenhower later issued a statement saying that the federal social security system warrants study. He stated:

> "This analysis should encompass not only the distribution of costs between the state and the federal government, but also the operation and coverage of the system itself. It is a proper function of government to help build a sturdy floor over the pit of personal disaster. . . . However, we are equally committeed to carrying out that great program efficiently and with greatest benefit to those it is designed to help."

Meanwhile, Daniel A. Reed, chairman of the House Ways and Means Committee, has appointed a seven-man subcommittee to make an "extensive study" of the entire social security system. It is the hope of Representative Reed that no legislation will be enacted in this field until the study is completed.

SURVEY SHOWS GP FARES WELL

According to the seventh *Medical Economics* survey, the average general practitioner in the United States is better off financially than at any time in the past.

That fact came as the result of answers to questionnaires sent to general practitioners last April by *Medical Economics* magazine. These doctors constitute a representative cross-section of the profession, and the information they supplied covers many phases of the economics of private medical practice in America, the magazine contends.

This information, as reported in "Public Health Economics," shows that "the independent GP reports an average gross income, for instance, of $23,766 for 1951. His net income in that year, before taxes, was $14,098—a rise of almost 50 per cent since 1947, and of more than 100 per cent since 1943."

Another factor is apparent from the survey:

> "Meanwhile, the financial gap that once separated him from his specialist colleague is narrowing. In 1943, he netted little more than half as much as the average specialist. In 1947, he netted about two-thirds as much. Nowadays he nets about four-fifths as much."

Increase Analyzed

Reasons for the fact that the general practitioner's increase in income are stated in the survey: "For one thing, he puts in longer hours than most other doctors—an average of sixty-two a week. So when his income is figured on an hourly basis, it becomes a shade less impressive. . . . Then, too, consider the brisk working pace of the G.P. He sees thirty-one patients in a typical day. . . . His total operating costs amount to $9,668—or 41 per cent of his gross from practice. Office rent and automobile upkeep . . . are big items; but salaries, drugs, and supplies are even bigger, accounting in the aggregate for more than half his total professional outlay."

Income in "Dribbles"

However, the report states the income of the general practitioner comes to him in "dribbles" which rather offset the value of his expanded facilities and increased income. The report explains:

> ". . . today's GP still gets most of his income in dribbles: a median of $3 for an office call, $5 for a house call, $6 for a night call. Fortunately, he's been collecting more of his accounts of late; he now actually gets about 85 per cent of the money his patients owe him—a big improvement over the depression years, when he thought himself lucky to get 70 per cent."

Insurance Payments Aid

Not all of the doctor's income comes directly from his patients. The report notes that payments from Blue Shield and other medical-surgical plans are becoming more and more important to the general practitioner. For instance, in 1951, these plans paid him an average of $2,136, which amounts to about two-thirds of the amount that such plans paid the average specialist.

Comparisons on a general economic basis were made between the specialist and the general practitioner. The survey reports them as follows:

> "(1) Collections are somewhat less of a problem to the specialist than to the GP. The average specialist collects 88 per cent of his accounts (as against the GP's 85 per cent), and takes in $3,206 a year from Blue Shield and other health plans (compared with the GP's $2,139).
>
> "(2) The average specialist, like the average GP, reaches his income peak between his tenth and nineteenth years in practice. His income falls off rather steadily after that.
>
> "(3) The highest incomes for specialists show up in cities of 50,000-500,000; the lowest, in places of under 50,000 and in very large metropolitan areas. . . ."

Of the million hospital beds needed during the next 15 or 20 years, two-thirds will be for the chronic sick, including mental and tuberculous patients.—A. P. Merrill, M.D., *New York State Medical Journal,* October 1, 1952.

Julian F. DuBois, M.D., Secretary

LICENSE OF MINNEAPOLIS PHYSICIAN REVOKED FOR NARCOTIC VIOLATION

Re United States of America vs. Russell R. Heim

On February 13, 1953, the medical license of Russell R. Heim, M.D., sixty-six years of age, Wesley Temple Building, Minneapolis, was revoked by the Minnesota State Board of Medical Examiners. Dr. Heim's license was revoked following his conviction in the United States District Court at Minneapolis. A jury found Dr. Heim guilty on 229 counts in the indictment returned against him by the grand jury alleging violations of the Harrison Narcotic Act. On November 10, 1952, Dr. Heim was sentenced to a term of four years in a Federal Prison by the Hon. Gunnar H. Nordbye, Judge of the United States District Court. Dr. Heim is serving his sentence at the United States Reformatory at Milan, Michigan.

Dr. Heim, at the time of his conviction, was the Coroner of Hennepin County. He received his M.D. Degree in 1910 at the University of Illinois. He was licensed in Minnesota by reciprocity in 1919.

LICENSE OF BELGRADE, MINNESOTA, PHYSICIAN SUSPENDED FOR THREE YEARS

Re George F. Engstrom, M.D.

On February 14, 1953, the license to practice medicine held by George F. Engstrom, M.D., forty-nine years of age, Belgrade, Minnesota, was suspended by the Minnesota State Board of Medical Examiners for a period of three years. Dr. Engstrom was found guilty by the Minnesota State Board of Medical Examiners of immoral, dishonorable and unprofessional conduct, as defined by law. Dr. Engstrom admitted that between the 1st day of January 1949 and the 18th day of June 1952, he had prepared "numerous fictitious, fraudulent and excessive claims for remuneration for professional services * * *." The fictitious, fraudulent and excessive claims made out by Dr. Engstrom were submitted to various insurance companies and other groups covering hospital and medical care benefits, including Blue Cross and Blue Shield.

It was the opinion of the Minnesota State Board of Medical Examiners that Dr. Engstrom's misconduct warranted a permanent revocation of his license. However, in view of the fact that Dr. Engstrom made full and complete restitution to all of the insurance companies involved, as well as to Blue Cross and Blue Shield, some measure of leniency was extended to him. The Medical Board warned, however, that such leniency may not be extended in the future if there is evidence that other physicians in Minnesota are involved in similar practices. Dr. Engstrom, in connection with the same matter, on July 14, 1952, entered a plea of guilty in the District Court of Ramsey County, to an information charging him with grand larceny in the second degree. Dr. Engstrom is to be sentenced on May 4, 1953, for that offense.

Dr. Engstrom was born in Sweden on April 5, 1903, and received his M.D. degree from the University of Minnesota in March 1928. He was licensed by the Minnesota State Board of Medical Examiners in July 1927, by examination upon receiving his Bachelor of Medicine Degree. He has been located at Belgrade, Minnesota, since August 1928.

SOCIAL EVENTS

MONDAY, MAY 18

Luncheons

American Medical Women's Association, Inc., Minnesota Chapter

12:15 p.m., Women's City Club

Make reservations through the secretary, Dr. Catherine Burns, 201 S. Broadway, Albert Lea, or Dr. Nellie Barsness, 540 Lowry Medical Arts Building, St. Paul 2.

Open to all visiting women doctors. Dr. Marie Bepko will discuss the International Convention in Vichy, France, and will illustrate her talk with colored slides.

Minnesota Medical Foundation

12:15 p.m., Casino, Hotel Saint Paul

Speaker: Dr. E. T. Bell, Emeritus Professor of Pathology, University of Minnesota, discussing some of the past history of the Medical School.

Tickets should be obtained from Dr. Wesley W. Spink, University Hospitals, Minneapolis 14. Price $1.75.

Dinners

Minnesota Chapter, American Academy of General Practice

5:00 p.m., Social Hour, Fiesta Room, Hotel Lowry

6:00 p.m., Dinner, Main Ballroom, Mezzanine, Hotel Lowry

Speakers: Dr. Harold S. Diehl, Dean, Medical School, University of Minnesota; Hon. C. Elmer Anderson, Governor of Minnesota; Congressman Walter Judd, M.D.

Tickets at $5.00 each should be obtained in advance from Dr. Emil J. Fogelberg, 45 N. Snelling Avenue, St. Paul. Open to all physicians.

Minnesota Radiological Society

7:30 p.m., Minnesota Club, 317 Washington St.

Speaker: Dr. Joseph C. Bell, President, Radiological Society of North America, Louisville, Kentucky, who will discuss "The Private Practice of Radiology."

Inhibition of Excess Parasympathetic Stimuli in Peptic Ulcer with Banthīne®

Medical literature now contains more than 200 references to the beneficial role of Banthine Bromide (brand of methantheline bromide) as evidenced by a marked healing response of peptic ulcers. Rapid symptomatic improvement, particularly with reference to pain relief, is followed by roentgenographic demonstration of crater filling.

The therapeutic action of the drug in decreasing hypermotility and hyperacidity, together with the remarkable early subjective benefit, is indeed a desired approach in ulcer management.

Treatment is individualized to the patient's needs. One or two tablets (50 to 100 mg.) is administered every six hours, around the clock, in conjunction with appropriate diet control and antacid medication as indicated.

Banthine is accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Searle: Research in the Service of Medicine.

ST. JOSEPH'S HOSPITAL CENTENNIAL

The following scientific program, in celebration of the 100th anniversary of the founding of St. Joseph's Hospital, Saint Paul, will be held in the Saint Paul Auditorium on the morning and afternoon of Saturday, May 16, 1953. A banquet in the evening will be held at the Saint Paul Hotel. Physicians are cordially invited to attend the sessions, and the banquet will be open to the public.

Sunday, May 17, will be devoted to religious services at the Saint Paul Cathedral in the morning, with a program of addresses at St. Joseph's Hospital in the afternoon.

Morning Session—9:00–12:00 M.

Presiding: Justus Ohage, M.D.

Invocation—The Reverend Francis W. Curtin, Bishop's Representative for Hospitals, Director of Diocesan Bureau of Charities

Message from the Minnesota Medical Association—O. J. Campbell, M.D., President, Minnesota Medical Association

Message from the Ramsey County Medical Society—Philip F. Donohue, M.D., President, Ramsey County Medical Society

"Humoral vs. Nervous Control of the Gallbladder"—Edward Boyden, M.D., Professor and Chief, Department of Anatomy, University of Minnesota

"The X-Ray Diagnosis of Gallbladder Disease"—Byrl R. Kirklin, M.D., Chairman of the Section of Radiology, Mayo Clinic, Rochester, Minnesota

"Coronary Disease and the Gallbladder"—Thomas J. Dry, M.D., Chairman of the Section of Cardiology, Mayo Clinic, Rochester, Minnesota

"Indications and Precautions in Cholecystectomy"—Warren H. Cole, M.D., Professor of Surgery, University of Chicago, Illinois

"Tissue Permeability"—William Boyd, M.D., Professor of Pathology, University of British Columbia

Intermission—11:10–11:20 A.M.

Presiding: O. J. Campbell, M.D.

President of Minnesota State Medical Association

"Experiences in Mass Photofluorography"—Richard Trail, M.D., London, England

"Coagulation of the Blood"—Armand J. Quick, M.D., Professor of Biochemistry, Marquette University

Afternoon Session—2:00–4:00 P.M.

Presiding: Eugene M. Scott, M.D.
Chief of Staff, St. Joseph's Hospital

Invocation—The Reverend Joseph Kuncl, Director of Archdiocesan Council of Catholic Nurses, Chaplain of St. Joseph's Hospital

"The Development of Bronchoscopy"—Chevalier L. Jackson, M.D., Professor of Otolaryngology, Temple University, Philadelphia

"Psychiatry and Religion"—Francis J. Braceland, M.D., Psychiatrist-in-Chief, The Institute of Living

"The Discovery of Penicillin"—Sir Alexander Fleming, M.D., Nobel Prize Winner in Medicine

Announcements

Intermission—3:00–3:20 P.M.

"Women in Medicine"—Burgess Lee Gordon, M.D., President, Woman's Medical College, Philadelphia, Pennsylvania

"The Discovery of Cortisone"—Philip S. Hench, M.D., Nobel Prize winner in Medicine, Department of Medicine, Mayo Clinic, Rochester, Minnesota

Evening Activities—7:00 P.M.

Centennial Banquet—Continental Room, Hotel Saint Paul

Toastmaster: The Very Reverend George E. Ryan

Greetings from Civic and Professional Representatives

The State of Minnesota
The City of Saint Paul
American Medical Association
  President Louis H. Bauer, M.D. (tentative)
American College of Surgeons
  President Harold L. Foss, M.D.
American College of Physicians
  President LeRoy H. Sloan, M.D.

Address by The Most Reverend John Gregory Murray, Archbishop of Saint Paul

Morning Services—11:00 A.M.

Solemn Pontifical Mass and Sermon—The Most Reverend John Gregory Murray, Archbishop of Saint Paul, St. Paul Cathedral

Afternoon Program—2:30–3:30 P.M.

St. Joseph's Hospital

"The Place of the Hospital in the Community"—Right Reverend Mngr. C. A. Towell, President of the Catholic Hospital Association

"The Spiritual Concept of Hospital Care"—The Reverend John J. Flanagan, S.J., Executive Director, The Catholic Hospital Association

INTERNATIONAL ACADEMY OF PROCTOLOGY

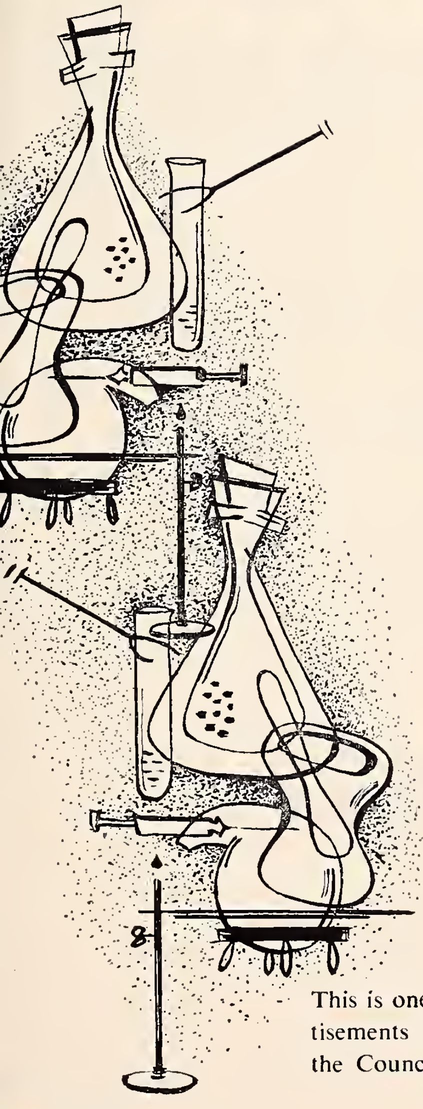
All physicians are cordially invited to attend the Fifth Annual Convention of the International Academy of Proctology to be held at the Plaza Hotel, New York City, May 29, 30 and 31, 1953, directly preceding the American Medical Association meeting. The meeting this year will be extended to include a Surgical Clinic and Seminar at Jersey City Medical Center under the direction of Dr. Earl J. Halligan. The "Wet Clinic" and Seminar will be on May 28. An extensive Motion Picture Seminar of Proctologic Surgery (including office techniques) will be held on May 31. All scientific papers will present the latest developments in proctology and gastroenterology.

Because general practitioners, as well as gastroenterologists and proctologists, face proctologic problems in their daily practice, much of the program has been planned to answer their questions.

There is no fee for attendance at the annual convention of the International Academy of Proctology. These conventions, as well as all other activities of the Academy, are directed toward the further development

(Continued on Page 404)

What is the status of ____?



Many times you have asked yourself, "Is the indicated drug Penicillin . . . Chloramphenicol . . . Aureomycin . . . Sulfadiazine . . . a combination . . . or what?" This same problem may confront you many times . . . not only with the antibiotics—but actually in any specific field where there are numerous drugs . . . and you are faced with the problem of determining which might be the therapy of choice for a given condition.

The need for such clarification has always been apparent to the Council on Pharmacy and Chemistry of the American Medical Association. Its frequent publication of special status reports in The Journal is designed to help answer such questions for you.

Information about new drugs—clinically proved indications . . . experimental uses . . . correct dosages . . . contra-indications . . . and similar facts—is frequently presented by the Council. Its announcements of newly accepted products also help keep you up-to-date on new and useful drugs. These notices which appear in The Journal almost every week can be a definite guide to you in knowing what preparations are Council accepted . . . how they are best used . . . and how they can be most effective in your daily practice.

Insistence on Council accepted products is one reliable guide to clinically tested products.

This is one of a series of advertisements designed to explain the Councils' functions to you.

of proctology. All physicians interested in proctology are therefore invited and welcomed to the annual meeting.

The program is available upon request to the Executive Offices of the International Academy of Proctology, 43-55 Kissena Blvd., Flushing, New York.

AMERICAN COLLEGE OF ALLERGISTS

The annual conclave of the American College of Allergists will be held this year at the Conrad Hilton Hotel in Chicago, April 24 to 29.

The first four days will be devoted to instruction under the tutelage of recognized authorities and the last three to a discussion and reporting of recent advances in the field of allergy by the investigators themselves. For detailed information write the American College of Allergists, La Salle Building, Minneapolis 2, Minnesota.

NATIONAL GASTROENTEROLOGICAL ASSOCIATION

The National Gastroenterological Association will give its Fifth Annual Course in Postgraduate Gastroenterology at the Hotel Biltmore, Los Angeles, October 15, 16, 17, 1953.

The course will again be under the direction of Dr. Owen H. Wagensteen, Professor of Surgery at the University of Minnesota Medical School, and Dr. I. Snapper, Director of Medical Education at the Cook County Hospital, Chicago. Distinguished faculty members from the medical schools in and around Los Angeles will provide the program.

Further information may be obtained from the National Gastroenterological Association, 1819 Broadway, New York 23, New York.

AMERICAN CONGRESS OF PHYSICAL MEDICINE AND REHABILITATION

The Midwestern Section of the American Congress of Physical Medicine and Rehabilitation will hold its spring meeting at the Center for Continuation Study of the University of Minnesota from 9:30 a.m. to 5 p.m., Friday, May 1, 1953. Physicians are cordially invited to attend. Anyone wishing for further information may obtain it from the secretary, G. K. Stillwell, M.D., 2333 Priscilla St., Saint Paul 8, Minnesota.

INDUSTRIAL MICROBIOLOGY INSTITUTE

The sixth annual Industrial Microbiology Institute will be held at Purdue University, June 22-27, 1953. The program is designed for scientists in industrial plants and others interested in the identification of fungi and the problems of fungus control.

In addition to the usual lectures and laboratory sessions, which are scheduled daily during the mornings

Our Most Sincere Congratulations to all of the Physicians of Minnesota on the occasion of the 100th anniversary of the founding of the

Minnesota State Medical Association

Minnesota Physicians have made phenomenal progress in all branches of medicine, have ministered untiringly to the health and happiness of their fellow men, are appreciated and loved by all, have achieved fame and renown at home and abroad for their Society and their State.

Again we say Congratulations.

and afternoons, a series of evening lectures will be given by outstanding specialists in the field of mycology, according to Dr. C. L. Porter, director of the institute.

These speakers include Dr. Virgil G. Lilly, professor of physiology at West Virginia, on "The Influence of Vitamins and Growth Factors on the Growth and Sporulation of Fungi"; Dr. William J. Robbins, director of the New York Botanical Garden, "Inhibition of Bacterial Viruses."

Dr. James G. Horsfall, director of the Connecticut Agricultural Experiment Station, "Fungicide Testing"; Dr. Radcliffe F. Robinson, assistant supervisor of biological research, Battelle Memorial Institute, "The Application of X-Ray Techniques to Industry"; and J. H. Richardson, Armour and Company, Chicago, "Mold Problems of the Food Industry."

The regular laboratory work will include the study of fungus classification, mucorales, ascomycetes, aspergilli, penicillia, actinomycetes, yeasts, and unknown fungi. Students will become sufficiently familiar with the terminology to read mycological literature.

Dr. John S. Karling, head of the department of biological sciences at Purdue, and other staff members will assist in directing the course.

BOARD OF EDUCATION EXAMINATION

Application forms for examination by the Board of Education of the city of New York for the position of School Chief Medical Director may be obtained from Dr. Jacob Greenberg, Associate Superintendent in Charge of Personnel, Room 510, 110 Livingston Street, Brooklyn 1, New York.

A fee of $10.00 is required upon scheduling of the tests. An applicant must be under the maximum age of fifty years, be graduated from an approved medical school or medical college and hold a license to practice medicine in the State of New York, and be certified as a diplomate of the American Board of Internal Medicine. Ten years' experience of approved and appropriate practice, nine months of which shall have been an internship in a hospital approved by the American Medical Association, is required; this experience must include or be supplemented by satisfactory administrative and supervisory experience over a period of two years. (In lieu of these requirements, a candidate may offer five years of experience as School Medical Inspector-Personnel in the public schools of the city of New York under regular license and appointment.

Questions regarding eligibility should be addressed to: Mr. Arthur Klein, Examiner-in-Charge, Board of Examiners, 110 Livingston Street, Brooklyn 1, New York.

FIRST INTERNATIONAL CONVENTION OF X-RAY TECHNICIANS

The First International Convention of X-Ray Technicians will be held in Toronto, Canada, at the Royal York Hotel, June 28 through July 2. The convention is sponsored jointly by The Canadian Society of Radiological

Technicians and The American Society of X-Ray Technicians.

Refresher courses will be offered for two hours each morning. The afternoon sessions will be devoted to joint sessions of the CSRT and ASXT, at which time technical papers and essays will be presented by technicians of both societies and by distinguished radiologists. Two Memorial Lectures will be given—Welch Memorial Lecture (Canadian) by E. A. Petrie, M.D., Director, Department of Radiology, St. Joseph's Hospital, St. John, New Brunswick, Canada; and the Jerman Memorial Lecture (American) by Russell H. Morgan, M.D., Professor of Radiology, The Johns Hopkins University, Baltimore, Maryland.

One need not be a member of either organization to attend. For further information, write Beatrice Hurley, R.T., Registrar, St. Catherine Hospital, East Chicago, Indiana.

CENTRAL ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

The Central Association of Obstetricians and Gynecologists announces the election of the following officers:

President—W. O. Johnson, M.D., Louisville, Kentucky
President-Elect—Harold C. Mack, M.D., Detroit, Michigan
Vice President—Arthur B. Hunt, M.D., Rochester, Minnesota
Secretary-Treasurer—Harold L. Gainey, M.D., Kansas City, Mo.
Assistant Secretary—Woodard D. Beacham, M.D., New Orleans, La.

These officers will serve until the end of the annual meeting which will be held at the Shamrock Hotel, Houston, Texas, on November 5, 6, and 7, 1953.

The business office of the Central Association of Obstetricians and Gynecologists is located in Suite 602, 116 So. Michigan Avenue, Chicago 3, Illinois. The office of Dr. Harold D. Gainey, Secretary-Treasurer, is located at 4635 Wyandotte Street, Kansas City, Missouri.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The regular meeting of the Society was held at the Town and Country Club in Saint Paul, Tuesday evening, March 10, 1953.

The scientific program was as follows: Speech and Hearing Problems in Child Psychiatry Practice

Louis L. Flynn, Jr., M.D.
(inaugural thesis)

The Effect of Iproniazid, a Derivative of Isonicotinic Acid Hydrazide, Upon the Behavior of Long-Term Mental Patients

Gordon R. Kamman, M.D,
John W. Freeman, M.D.
(by invitation)
Rubel J. Lucero, Ph.D.
(by invitation)

E. STARR JUDD LECTURE

The twentieth E. Starr Judd Lectureship will be given by Dr. Charles B. Huggins, Professor of Surgery, University of Chicago, Chicago, Illinois, Thursday evening, May 7, 1953, at 8:15 p.m. in the Amphitheater, Owre Hall (formerly Medical Sciences) sponsored by

MINNESOTA STATE MEDICAL ASSOCIATION

Welcome to Saint Paul

For Your 1953 Convention

HOTEL *Saint Paul* **HOTEL** *Lowry*

the Medical School. Dr. Huggins' subject is "The Endocrinology of Mammary Cancer."

The late E. Starr Judd, an alumnus of the Medical School of the University of Minnesota, established this annual lectureship in Surgery a few years before his death.

MSMA COMMITTEE ON CONSERVATION OF HEARING

This announcement is made to inform physicians that the Committee on Conservation of Hearing is making a survey of Minnesota to determine the incidence of handicapping hearing loss among the residents of the State.

This survey is being made through school and country public health nurses and local health officers. Members of the committee have accepted assignments to conduct this survey as follows:

Dr. John Cameron—Crookston. Counties: Kittson, Roseau, Lake of the Woods, Marshall, Beltrami, Polk, Pennington, Red Lake, Clearwater, Norman, Mahnomen, Hubbard, Cass, Clay, Becker, Wadena, Crow Wing, Wilkin, Ottertail, Traverse, Grant, Douglas.

Dr. Anderson Hilding—Duluth. Counties: Koochiching, St. Louis, Lake, Cook, Itasca, Aitkin, Carlton, Pine, Kanabec.

Dr. Charles E. Connor—Saint Paul. Counties: Isanti, Chisago, Washington, Ramsey, Dakota.

Dr. Conrad J. Holmberg—Minneapolis. Counties: Wright, Anoka, Hennepin, Carver, Scott.

Dr. Joseph Gaida—Saint Cloud. Counties: Big Stone, Lac Qui Parle, Yellow Medicine, Chippewa, Swift, Stevens, Pope, Renville, Kandiyohi, Stearns, Todd, Morrison, Mille Lacs, Benton, Sherburne, Meeker, McLeod, Sibley.

Dr. J. Donald Sjoding—Mankato. Counties: Rock, Pipestone, Lincoln, Nobles, Murray, Lyon, Redwood, Cottonwood, Jackson, Martin, Watonwan, Brown, Nicollet, Blue Earth, Le Sueur.

Dr. Kinsey Simonton—Rochester. Counties: Rice, Goodhue, Wabasha, Waseca, Steele, Dodge, Olmsted, Winona, Faribault, Freeborn, Mower, Fillmore, Houston.

The Committee is preparing a pamphlet that will supply factual information regarding the status of such therapy as radium treatment, the fenestration operation, dental treatment designed to open the bite, et cetera. Statements will also be included regarding the role of the hearing aid and speech reading in the rehabilitation of those who cannot be helped by medical or surgical means. This information will be available without charge for those requesting it.

Lawrence R. Boies, M.D.
Chairman

CONTINUATION COURSES

The University of Minnesota will present a continuation course in *Radiology for General Physicians* May 21 to 23, 1953, under the direction of Dr. Leo G. Rigler, Professor and Head, Department of Radiology. Registrants for the course will spend most of their time in the University Hospital Department of Radiology reading films and carrying out procedures in association with

University of Minnesota

Nursing and College

A FASCINATING CAREER!

Students! The Nursing Programs of the University of Minnesota offer you a wonderful chance to combine a good college education with sound practical experience. For a professional or practical nursing career, for part-time nursing, and as excellent preparation for running a home and raising a family, you'll find nurses' training will be useful all your life.

Programs of the University of Minnesota School of Nursing

1. Professional Basic program prepares you for responsible positions in leading hospitals and other health agencies. B.S. degree awarded. 16 quarter program, start Pre-Nursing Courses any quarter. Admission to School of Nursing fall and spring quarters.

2. Advanced Programs prepare graduates to be clinical specialists, teachers, administrators.

3. Practical Nursing Programs qualify you for practical nursing positions in 4 to 6 quarters. You'll want to investigate the possibilities of these programs fully.

Write for further information to Miss Katharine J. Densford, Director, University School of Nursing, Minneapolis 14, Minnesota.

University of Minnesota School of Nursing

members of the faculty of that department. A minimum of didactic material will be presented. Because of the nature of this course, registration will be strictly limited. Early application is therefore suggested. Accommodations will be available in the Center for Continuation Study as usual.

* * *

Electrocardiography will be the subject of a continuation course for general physicians which will be presented by the University of Minnesota next June 8 to 12. Emphasis will be placed on practical experience in the interpretation of electrocardiograms. Each registrant will have an opportunity to read approximately 200 tracings under the supervision of the teaching staff. Separate sessions are being planned for those who consider themselves "beginners" in electrocardiography. The faculty for the course will consist of members of the staff of University of Minnesota Medical School and the Mayo Foundation.

POSTGRADUATE CANCER AND HEART DISEASE SEMINARS

Two postgraduate seminars on cancer and heart disease are scheduled for the physicians in the western part of Minnesota this spring. One seminar will be held in Marshall on March 31. Seven Tuesday evening sessions extending through May 12, are alternately scheduled for the Minnesota Cafe and the New Atlantic Hotel, in Marshall.

In Morris, the site of the second seminar, six sessions will be held in the Stevens County Hospital beginning April 8.

All physicians in these areas are invited to attend. The meetings will be interesting and profitable. There is no fee for the series of lectures.

Both Marshall and Morris seminars are sponsored by the Minnesota Department of Health, Minnesota Medical Association, University of Minnesota, Minnesota Cancer Society and the Minnesota Heart Association in conjunction with the Lyon and Lincoln County Medical Society and the West Central Minnesota Medical Society, respectively.

FAMILY DOCTORS' DAYS

The first in a series of *Family Doctors' Days* will be presented at the University of Minnesota Hospitals, April 29. The members of the Medical School faculty are eager to have as many physicians as possible attend this program for they look forward to the opportunity of exchanging ideas and problems.

The April 29 program will be a very informal one presented by the Department of Medicine and will feature the following:

12:00 noon	Luncheon with Department of Medicine staff	
2:00 p.m.	Antibiotics in Medical Practice	W. W. Spink
3:00 p.m.	Ward Rounds	C. J. Watson
4:30 p.m.	Clinical-Pathological Conference	C. J. Watson and staff

All physicians are invited to attend.

STEELE COUNTY MEDICAL SOCIETY

At the annual meeting of the Steele County Medical Society, Dr. R. J. Wilkowske was elected president; Dr. J. A. McIntyre, vice president, and Dr. J. F. Schaefer, secretary-treasurer. Dr. E. Q. Ertel, Ellendale; Dr. C. T. McEnaney and A. J. Olson, of Owatonna, were named censors. Dr. C. Lundquist, of Owatonna, was elected delegate to the annual convention of the Minnesota State Medical Association, with Dr. T. W. Stransky, of Owatonna, as alternate.

"YOUR DOCTOR" FILM

In 1952 more than 20 million theater goers in the United States and Canada saw a movie entitled "Your Doctor," which was produced by Louis de Rochemont with the assistance of the AMA. This film is valuable as a Public Relations activity to be sponsored by county or state medical associations. Society PR committees or Medical Auxiliaries may purchase the film and loan it to local groups or commercial theaters, or they may obtain the film from Modern Talking Picture Service, Inc., at the nearest distribution center by paying postage and insurance charges only. The nearest distributor in Minnesota is Mr. A. C. Holmgren, Elliott Film Company, 1110 Nicollet Avenue, Minneapolis.

PR committees of medical societies can contact local movie houses and use all facilities of the society to build an audience. Promotional aids in publicizing the movie may be obtained from the AMA.

Woman's Auxiliary

PLANS COMPLETE FOR 31ST ANNUAL MEETING

Mrs. C. L. Sheedy, President

The Woman's Auxiliary to the Minnesota State Medical Association will hold its thirty-first annual meeting on May 18, 19 and 20, in conjunction with the 100th Anniversary meeting of the Minnesota State Medical Association on those dates in Saint Paul, where an interesting program is planned.

The meeting will begin with registration at 9:00 a.m. each morning. Auxiliary headquarters will be the Hotel Lowry.

The Executive Board meeting will begin at 10:30 a.m., Monday, May 18, at the Minnesota Club, with a luncheon following at 12:30 p.m. The annual tea, held in honor of state officers, will begin at 3:30 p.m. at the International Institute, where refreshments of many national origins will be served.

The annual business meeting, open to all members of the Auxiliary, is scheduled for 10:00 a.m., Tuesday, May 19, and will take place in the Fiesta room of the Hotel Lowry. The annual luncheon for all members is to be held at 1:00 p.m. in the Terrace, Hotel Lowry. Dr. Gordon R. Kamman, Associate Professor of Nervous and Mental Diseases, University of Minnesota, and Deputy Commissioner of Mental Health for the State of Minnesota, will speak on "Minnesota's Mental Health Program." Installation of officers and presentation of the new Auxiliary president, will follow. All board members will attend the post-convention board meeting following this meeting.

The annual breakfast for all Auxiliary members will be held on Wednesday morning, May 20.

Your president would like to take this opportunity to urge you to make plans now to attend this important Auxiliary meeting. It offers a chance to become better acquainted with Auxiliary procedures and gives doctors' wives from throughout the state a chance to take part in all vital discussions and decisions made at the convention. Please remember the dates May 18, 19 and 20. Your program will be sent you in advance of the meeting and will include a reservation card so you may make arrangements for attending events at the thirty-first annual convention.

FREEBORN AUXILIARY AIDS CIVIL DEFENSE

Members of the Freeborn County Medical Auxiliary are devoting time to training and aid in the civilian defense program. Many members are taking the home nursing course offered by the Civil Defense department. Mrs. R. F. Schmidt, an Auxiliary member, will teach this home nursing training course.

This action was taken at the February meeting of the auxiliary. Members met at the home of Dr. J. P. Person, and were shown two civil defense films by Judge Norris Peterson. The films dealt with biological warfare and atomic attack.

Other activities of the Freeborn auxiliary include cooperation in the Red Cross blood program, aiding in the hospital shop and interesting girls in the student nurse program.

In Memoriam

WILLIAM ALBERTUS COVENTRY
1876-1953

On February 8, 1953, in Duluth, death took from our roster, a man of unusual devotion to our guild. It is impossible to do justice to his attainment within the limits of this record. W. A. Coventry came to Duluth just at the turn of the century. For over fifty years he was recognized as a standard bearer of all that is best in medicine in that challenging period. The great era of machines and mass production economy was on the way, not to mention two overwhelming world wars that put our social and economic structure to every possible test. It was to witness the gifts of science to medicine, marvelously increasing the range of the doctor's services, the while his personal prestige as a miracle man lessened because, as a patient recovering from pneumonia could say, "It was the penicillin that turned the trick."

A review of W. A. Coventry's life shows to what an unusual extent he was able to become a part of the leadership so important to our administrative and scientific departments and societies. In his long life, he illustrated the necessary adaptation of the profession to a great increase in medical specialties; to the expansion of our hospitals and the proportion of medical work done in offices and clinics. Social and economic trends, with the great depression of the early thirties, led to a great extension in medical relief. W. A. Coventry gave much time and thought to plans for meeting this exigency. The difficulties involved were such that much that had to be done could not be done by mass action, as for instance, in the prevention and treatment of acute transitory disorders. The profession of medicine had to accommodate to handling chronic disorders and disabilities with the aging factor ever in the ascendency.

It was this background that brought out in W. A. Coventry his great usefulness to our profession, through his unlimited fund of energy and judicious guidance. He was also willing to enter with avidity into the work of many non-medical groups and associations, that developed confidence in doctors as citizens and leaders, without which public health efforts would have been long delayed. He had also good business judgment and served on the directorate of The Northern National Bank in Duluth for many years, as well as on several other business enterprises. It is fitting to review briefly a few of the sequences and attainments in the life of W. A. Coventry that portray the sources of his type of leadership that invites emulation.

William Coventry was born in Brainerd, September 17, 1876. His father was a Northern Pacific Railroad engineer. The family later transferred to Duluth where William finished high school and made his future educational goal the University of Michigan, from which he graduated in Medicine in 1900. For one year he interned under the late well-known Walter Courtney, Chief Surgeon of the Northern Pacific Railway, at Brainerd. After a year, he joined another Michigan graduate, the late Dr. A. J. Braden, in a general and railroad practice in the Duluth West End. Doctor Braden was a meticulous surgeon, never sparing himself, and was responsible for some of the earliest and best development of hospitals in Duluth. His young associate found the elder man a tough taskmaster, but he was taught how to work, and to use his time and faculties most effectively. For example, he was introduced to a very heavy obstetrical practice in that rapidly growing and expanding portion of Duluth. In the course of his professional life, it was estimated that he brought into the world over 5200 babies! This early experience laid the foundation for his ultimate specialization in Obstetrics and Gynecology. To prepare for this, he spent part of 1910 and 1911 in graduate study in Vienna and Dublin. In later years, he made frequent visits to the various lying-in hospitals in our own country. At one time, he became quite familiar and skilled in the techniques of the famous Doctor Potter, of Buffalo, New York, who popularized his own method of obstetrical version. This limited field of Obstetrics and Gynecology was never sufficient, however, to demand all of Doctor Coventry's time or talents. He was very active in the early development of the American College of Surgeons; and in 1940 was a member of the Board of Governors.

Doctor Coventry made the expansion and development of Duluth's two major hospitals, St. Mary's and St. Luke's, one of his favorite labors. In 1951, he received from St. Mary's Hospital an illuminated scroll, commemorating this well-earned recognition for his teaching, his interest in staff meetings, pathological conferences and everything that pertained to wholesome staff organization. He served both hospitals, on occasion, as Chief of Staff. It was inevitable that anyone with his dynamic personality and willingness to serve should have fastened upon him such offices and appointments as the presidency of the St. Louis County Medical Society and then of the Minnesota State Medical Association. He also served as an active member of the Council of the State Medical Association and for one year was its chairman. He allocated much time to assisting in the organization and directing of the work of the Blue Cross, and later the Blue Shield. As to attending his official committee duties, he was no attendant by proxy. He seemed tireless in terms of travel. In that respect he shared the enthusiasm of such men as the late W. L. Burnap, of Fergus Falls, and of Bert Adams, still active in Hibbing, Minnesota. Between these men and a few others of their type, the naturally segregated northern portion of Minnesota was able to keep its medical needs adequately represented in the medical councils of the state.

Doctor Coventry extended his public service in civic affairs to many organizations, including the Duluth

North Shore Health Resort

Winnetka, Illinois

on the Shores of Lake Michigan

A completely equipped sanitarium for the care of
nervous and mental disorders, alcoholism and drug addiction
offering all forms of treatment, including electric shock.

SAMUEL LIEBMAN, M.S., M.D.
225 Sheridan Road **Medical Director** **Phone Winnetka 6-0211**

Chamber of Commerce, the Duluth Kiwanis Club, the Arrowhead Association and the Masonic Order. In all of these, he had official recognition. The 1949 Duluth Hall of Fame Award was given him with particular attention drawn to his medical guidance of The St. Louis County Welfare Board in the crucial period following the depression of the early thirties.

Doctor Coventry saw every advantage in working together with his fellow practitioners to make his home area a safe place in which to be sick. That was the keynote of his interest in the societies in which he had membership and in their various local and national meetings. He took his membership seriously. He was the best of listeners and aimed to miss nothing of tangible value. Staff conferences were never a drudgery, whether he was on the program or not. He enjoyed his position as one of the Minnesota delegates to the AMA, and his advice was often sought. He fell naturally into the spirit of co-operative enterprize, which led him to join with some others, as a founder of the association known as the Duluth Clinic in 1916. It was not easy for him either to write for publication or to speak extemporaneously. Therefore, much that he gave to the various organizations mentioned in the way of public service was worked out the hard way. It came entirely out of his brave and earnest heart and from his total integrity and honesty.

Doctor Coventry's first wife, the mother of his four children, fell a victim to influenza in 1918. He is survived by his present wife, Anna S., two sons and two daughters. Both sons are in the field of medicine: Dr. William D., an internist of Duluth, and Dr. Markham in Orthopedics at the Mayo Clinic, Rochester, Minnesota. The daughters, Mrs. John M. Harlow and Mrs. Frederick Norton, live in Tucson, Arizona, and El Paso, Texas, respectively. He is also survived by two sisters and a brother.

His life was characterized by tolerance. It has been said that it is well that but few men become leaders, because the attainment breeds aggressiveness, and with it, distasteful intolerance.

E.L.T.

FRANK P. FRISCH

Dr. Frank P. Frisch of Willmar, Minnesota, died March 8, 1953, of a heart attack.

Dr. Frisch was born in St. James, Minnesota, on April 27, 1884. He obtained his medical degree from the University of Minnesota in 1914 and interned at the University Hospital in Minneapolis.

He practiced at Kimball, Minnesota, from 1915 to 1917 and at Gibbon, Minnesota, from 1919 to 1923. In 1924, he took postgraduate work at the New York Postgraduate School. From 1925 to 1928, he practiced at Bismarck, North Dakota. From there he moved to Willmar.

Dr. Frisch was a member of the Minnesota Academy of Otolaryngology and Ophthalmology and of the American College of Surgeons. He was a member of the Kandyohi-Swift-Meeker County Medical Society and of the Minnesota State Medical Association and the American Medical Association.

SEVERIN HERMAN KOOP

Dr. Severin H. Koop of Richmond, Minnesota, died on February 5, 1953, at the University Hospital in Minneapolis.

Dr. Koop was born at Brainerd, June 24, 1898. He received his medical degree from the University of Minnesota in 1926 and interned at St. Mary's Hospital, Minneapolis, and in the hospital of the same name, Duluth, after which he became superintendent of the Richmond Hospital.

In 1927, Dr. Koop was married to Helen Beatrice Sehl. His widow and six children survive him.

Dr. Koop was a member of the Stearns-Benton County Medical Society, the Minnesota State Medical Association, the American Medical Association, the Midwest Hospital Association, and the American Academy of General Practice.

JOHN SILLIMAN MACHIE

Dr. John D. Gilbert of Carlton, Minnesota, died January 20, 1953, at the age of eighty-eight.

Dr. Gilbert was born July 5, 1864, in Stratford, Connecticut. He obtained his M.D. degree from the College of Physicians and Surgeons in Chicago in 1890 and moved to Carlton from Fond du Lac, Wisconsin, in 1909.

Dr. Gilbert practiced at Carlton until 1942 but continued to be the village health officer until 1949. He had been residing at the home of Mr. and Mrs. Roy Nordstrom since 1946.

RUSSELL JAMES MOE

Dr. Russell J. Moe, of Duluth, died on March 8, 1953, following a long illness.

Dr. Moe was born at St. James, Minnesota, April 21, 1902. He studied medicine at the University of Minnesota where he graduated in 1928. After interning at St. Luke's Hospital, Duluth, he took postgraduate work at the New York Lying-In Hospital and at the Washington University Medical School at St. Louis.

Dr. Moe was a member of the St. Louis County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was also a member of the Interurban Academy of Medicine, the Minnesota Society of Obstetrics and Gynecology, the Central Association of Obstetrics and Gynecology and the Minnesota Surgical Society, of which he was a past president.

Dr. Moe is survived by his wife, Virginia Palmer Moe, three sons and a daughter.

EDWARD MOREN

Dr. Edward Moren of Duluth, Minnesota, who formerly practiced surgery in Minneapolis, died February 27, 1953, at the age of seventy-seven.

Dr. Moren was born at Anoka, Minnesota, June 18, 1876. He graduated from the University of Minnesota Medical School in 1906 and interned at the Minneapolis

General Hospital. He took postgraduate work in surgery in Vienna from August, 1912 to August, 1913 and was Clinical Assistant Professor of Surgery at the University of Minnesota and Assistant Chief Surgeon at Minneapolis General Hospital. At one time he served as Chief of Staff at the Swedish Hospital in Minneapolis.

Dr. Moren was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, and the American Medical Association. He was also a fellow of the American College of Surgeons. He is survived by four daughters: Mrs. W. F. Johnson, Duluth; Mrs. Willard Stout, Los Angeles; Mrs. John Rothermel, Great Falls, Montana, and Mrs. George Fahlstrom, Buffalo, New York.

WALTER EARL RICHARDSON

Dr. W. E. Richardson died in Saint Paul, February 7, 1953. He had made Saint Paul his home for several years after practicing medicine in Minnesota and South Dakota for more than fifty years.

Dr. Richardson was born in Elgin, Minnesota, July 15, 1872. He graduated from Rush Medical College in 1896. He practiced for two years under Dr. G. J. Moe at Heron Lake, Minnesota. He practiced at Slayton, Minnesota, for twenty-one years until 1919 and, in 1913, founded the Murray County Hospital in that city. He practiced at Pipestone, Minnesota, from 1919 until December 1, 1931, and during that period was Commander of the American Legion Post of Pipestone. He then practiced at Philip, South Dakota, where he remained for six years. He retired in Rushford, Minnesota, in 1946 after practicing there eight years. During World War I, he was attached to Base Hospital 99 in the A.E.F.

Dr. Richardson was a one-time member of the Olmsted-Houston-Fillmore-Dodge County Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Richardson is survived by his wife, Fatima; a daughter, Mrs. F. C. Eustis of Saint Paul; three sons, Walter W., Superintendent of Schools in North Saint Paul; William H. of Jasper, Minnesota, and Dr. Robert J. of Saint Paul.

Of General Interest

Dr. Wesley W. Spink of the University of Minnesota Medical School delivered the Twenty-ninth Annual James Anders Lecture before the College of Physicians of Philadelphia, April 1.

* * *

Dr. E. A. Boyden, Professor of Anatomy at the University of Minnesota, addressed the opening session of the two-day course in Pathologic Physiology of the Lung, held in St. Louis, March 31, in conjunction with the annual meeting of the American Association of Pathologists and Bacteriologists.

* * *

Dr. Reynold A. Jensen, Professor of Pediatrics at the University of Minnesota, recently participated in a Postgraduate Assembly in Omaha, speaking on the subject, "The General Principles of Child Psychology." He also served in a panel discussion on child behavior.

* * *

Dr. N. M. Mensheha, a native of Ukraine, now an American citizen and a practicing physician in Forest Lake, spoke at the Forest Lake Township Farm Bureau monthly meeting, March 3. Dr. Mensheha described life in a a communist state.

* * *

Dr. Howard L. Horns, assistant dean of the University of Minnesota Medical School, was recalled to active duty with the Army Medical Corps, March 17. **Dr. William F. Maloney,** medical fellow, is serving as acting assistant dean during Dr. Horn's leave of absence.

Dr. Horns is the second member of the medical school staff to be activated since January 1. **Dr. Richard M. Magraw,** assistant professor of psychiatry and medicine, was recalled to active service in January.

* * *

Dr. John B. Sanford, recently returned from army medical service in Korea, spoke on conditions in Korea to the members of the St. Louis County Medical Society at the regular meeting, held March 12, at St. Mary's Hospital, Duluth.

* * *

Mrs. Roy Good, mother of the three Drs. Good—**Dr. Roy H., Dr. Thomas A.,** and **Dr. Robert A.,** all of Minneapolis—was chosen Mother of the Year for Minnesota. Mrs. Good, a Minneapolis elementary school teacher, was widowed twenty-nine years ago. Besides her three sons in the medical profession, another son, Charles, is working for his Ph.D. in psychology at the University of Minnesota.

* * *

Dr. J. F. DuBois was named Sauk Centre's "Citizen of the Year" March 10. He was awarded a plaque by the Sauk Centre Chamber of Commerce and his photograph will be hung in a special gallery in the city hall. Dr. DuBois is secretary of the State Board of Medical Examiners; in 1948 he was president of the National Federation of Medical Licensure, and in 1950 became the first Minnesotan named to the National Board of Medical Examiners. Dr. DuBois has always been active in local civic affairs until last year when he suffered a stroke and has been in retirement from his medical practice..

* * *

Dr. H. Herman Young, Mayo Clinic surgeon, showed colored slides of accident victims who have been treated at the Mayo Clinic, at a Farm and Home Safety Institute held at the Albert Lea High School, March 19.

* * *

Dr. J. M. Gacusana, recently from Hot Springs, South Dakota, opened a practice in Mahnomen, March 6.

* * *

Two former Saint Paul doctors—**Dr. Paul B. Magnuson,** secretary of the American College of Surgeons and former chief medical director of the Veterans Administration, and **Dr. Dean A. Clark,** general director of Massachusetts General Hospital—took part in a two-day forum at the annual meeting of the National Health Council, held in New York City, March 19 and 20.

* * *

Dr. M. H. Larson, who has been operating the hospital in Nicollet, began practice in Lake Benton in the new clinic there, April 1.

* * *

Dr. Bernard Street and **Dr. A. M. Nielsen,** of Northfield, broadcast over local station, KDHL, February 13 and 17, emphasizing the need for blood donors contributing during the visit of the Red Cross mobile blood bank unit.

* * *

Dr. M. H. Bauer, of Winthrop, was re-elected chairman of the Sibley County Nursing Advisory Board at the annual meeting held February 3 in the courthouse.

* * *

Dr. Traugott J. Bloedel, of the Osseo Clinic, assisted with the immunization program in the public and parochial schools at Dayton, February 5.

* * *

Dr. Frederic Kottke, of the University of Minnesota Hospitals, was guest speaker at the annual meeting of the Isanti County Public Health Nursing Service, held February 11, in the Lutheran Church at Braham. Dr. Kottke presented a lecture on rehabilitation of patients sufferisg from crippling diseases such as arthritis, polio and spastic palsey. **Dr. S. G. Johnson,** of Isanti, presided over the meeting.

School, and **Dr. Reynold Jensen,** University of Minnesota, child psychiatrist, were the guest speakers at the last two seminar meetings of the Blue Earth Valley Medical Association. Dr. Bernstein, speaking at the February 12 meeting, dealt with the topic of cancer of the rectum and colon. Dr. Jensen, who spoke at the February 27 meeting, spoke on "The Psychiatric Aspects of Growing Children."

* * *

Dr. Orianna McDaniel, a woman pioneer in the medical field, has behind her fifty years of service with the Minnesota State Health Department. Dr. McDaniel earned her medical degree at the University of Michigan and came to Minneapolis in 1894 to intern at Northwestern Hospital, one of the few hospitals in the country that would accept a woman doctor in those days. Two years later she joined the Health Department. In 1907 Dr. McDaniel organized and headed the department's Pasteur Institute but by 1921 a new process for the treatment of rabies was developed so that local doctors could care for rabies patients, and the institute was abandoned. During World War I, Dr. McDaniel became acting director of the state's Division of Preventable Diseases, while Dr. A. J. Chesley, director, was in military service. She remained as head of the division under Dr. Chesley, ustil her retirement at the age of seventy-three years.

RECENT DENTAL LITERATURE ADVOCATES BAN ON THUMB SUCKING AND NAIL BITING

Cast from a children's dental clinic showing malocclusion due to thumb sucking

Authorities show developmental defects in dental occlusion when vicious habits are not treated. Children and adults alike are subject to these injurious mouth habits. Nagging and rebuke are psychologically unsound and serve only to focus attention on the habit. For efficient treatment on a reflex basis, prescribe

Dr. George Penn, of Mankato, was guest speaker at the February meeting of the Women's Auxiliary of Immanuel Hospital. Dr. Penn talked on, "Obstetrics and the New Hospital," showing drawings of the plans for the new obstetrics wing which is soon to be completed.

* * *

Dr. H. L. Smith, retired after twenty-seven years in the cardiology department of the Mayo Clinic, entered the printing and publishing business by purchasing the *Mantorville Express*, a weekly almost as old as Minnesota itself, recently. Dr. James Eckman, (Ph.D) associated with the publications department of the clinic, has been unofficially designated the technical adviser.

Switching from medicine to print and make-up for Dr. Smith is just a fulfillment of his hobby. During his years at the clinic, Dr. Smith spent many hours of spare time working in his basement print shop at a hobby that took him away from his work. He often collaborated with Dr. Eckman on printing projects. Dr. Eckman has made a hobby of type collecting as well as printing. He now owns some 300 cases of various type faces from many parts of the world. Some of his type dates back to 1690.

The *Mantorville Express* was founded in 1857 by John E. Bancroft who carted his outfit across the plains by ox team. The fortunes of the paper have paralleled those of the Dodge County seat which it served. As the town gradually lost its place, the paper dwindled in importance, circulation and income. However, the town people would not let their paper die entirely and up to November, 1952, it was operated as a co-operative project, being leased to various printers to operate. L. W. Jensen, who was currently leasing the paper, will continue as editor under the new publisher, Dr. Smith.

* * *

Dr. Earl Bigler was elected president of the Perham Chamber of Commerce recently. Dr. Bigler has been in practice in Perham since April 1, 1947 when he joined his brother, **Dr. Ivan Bigler**, there in his medical practice.

* * *

Dr. Jack Friedman of Mount Sinai Hospital, Minneapolis, was the guest speaker at a meeting of the Stearns-Benton Medical Society, February 19.

* * *

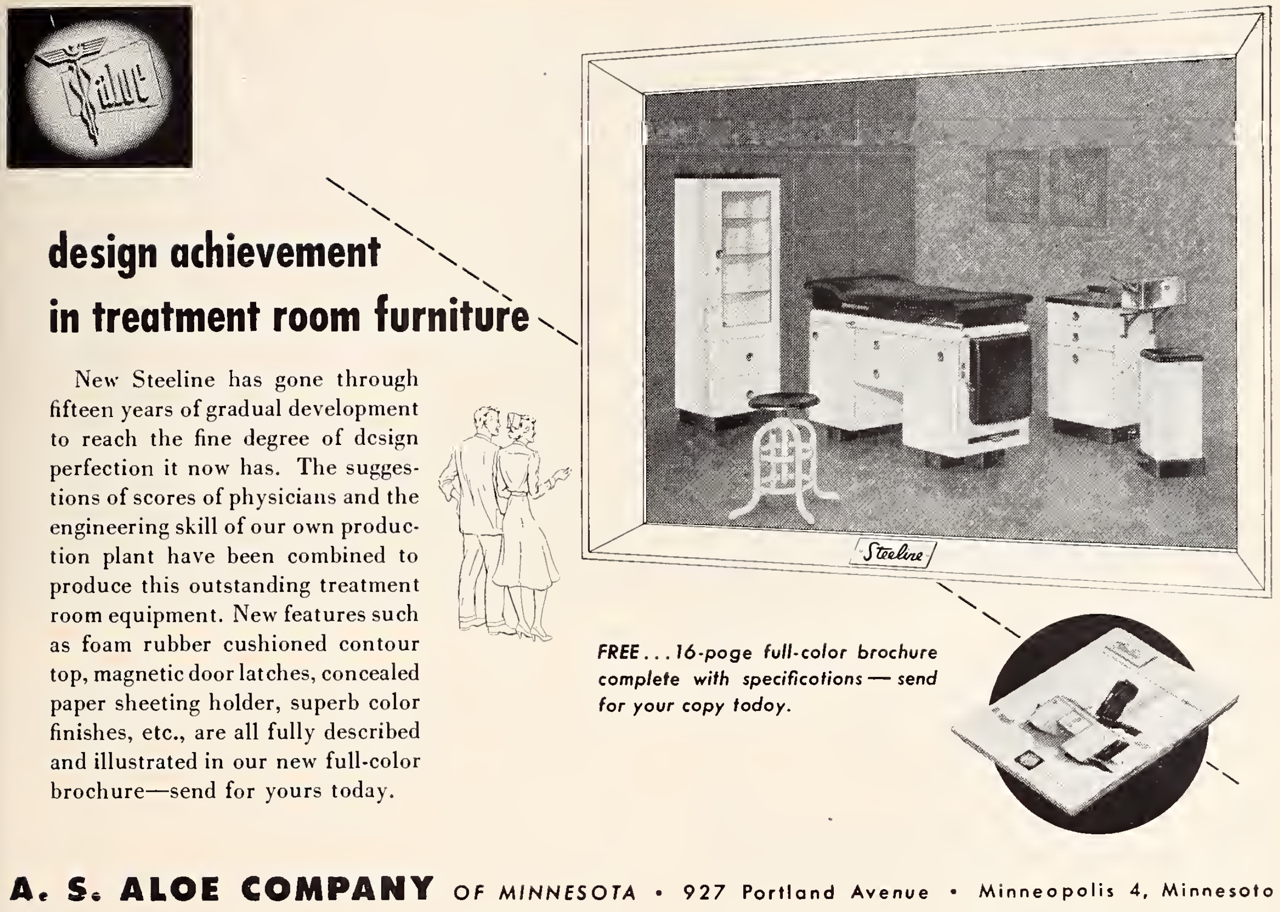
Dr. T. P. Mollers, of Soudan, was elected secretary of the Range Medical Society at a recent meeting of the staff. **Dr. Paul Reed** of Virginia, is president of the group which is composed of members from Duluth and Range communities.

* * *

Dr. John P. Dahlstet, Mankato, has been recalled to active duty with the Navy. He left for assignment at the Marine corps air station at Miami, Florida, February 24.

* * *

Dr. F. W. Behmler, of Morris, has been appointed Stevens County United States Defense Bond chair-



design achievement in treatment room furniture

New Steeline has gone through fifteen years of gradual development to reach the fine degree of design perfection it now has. The suggestions of scores of physicians and the engineering skill of our own production plant have been combined to produce this outstanding treatment room equipment. New features such as foam rubber cushioned contour top, magnetic door latches, concealed paper sheeting holder, superb color finishes, etc., are all fully described and illustrated in our new full-color brochure—send for yours today.

man. As chairman, Dr. Behmler will co-ordinate efforts to meet the 1953 Stevens County goal of $360,000.

* * *

Dr. C. H. Coombs, of Cass Lake, moved into his new six-room medical building recently.

* * *

Dr. Walter Wells, of Jackson, president of the Southwestern Minnesota Medical Society, was injured in a car-truck collision, February 22, while he was making a sick call. Dr. Wells suffered a fractured pelvis. His car was demolished.

* * *

Dr. Owen Wangensteen, University of Minnesota Medical School professor, and member of the national and state boards of the American Cancer Society, attended a meeting of the American Cancer Society in Chicago, February 21, accompanied by three of his patients. The patients—Mrs. Catherine McKee, of Bemidji, Elias Lindeberg, of Minneapolis, and Mrs. Carrie Lang, of Saint Paul, appeared at the meeting to demonstrate medical advances made in recent years in cancer research.

* * *

Dr. McLemore Bouchelle, East Range Clinic of Virginia, spoke on "The Attitude of the Patient and his Family toward Cancer," to the Gillett Club of Eveleth, February 16.

Dr. Inge Eleanore Mook, Minneapolis, was a guest speaker at a general meeting of the American Association of University Women, held at Duluth, February 24. Dr. Mook is the recipient of the AAUW, Duluth branch international study grant for 1951-1952. Her topic was "Circle the World with Friendship." Dr. Mook received her medical degree in 1950 from the University of Goettingen in Germany and completed her internship in that country. She is now specializing in heart disease and diseases of the circulation of the blood at the Heart Hospital of the University of Minnesota Hospitals, Minneapolis.

* * *

Dr. W. A. Miller, of New York Mills, was honored after fifty-seven years of service at a testimonial banquet and program, February 17, sponsored by the local Lions Club. Besides serving the community as a physician, in his earlier days Dr. Miller was obliged to serve also as dentist and druggist, as the need arose. Dr. E. C. Hanson, toastmaster for the occasion, read a telegram from the Minnesota State Medical Association, congratulating Dr. Miller on his life-time of service in the medical profession. Dr. and Mrs. Miller were both cited for their contributions to community life in general.

* * *

Dr. and Mrs. E. J. Tanquist, of Alexandria, left in late February on a trip to Mexico, Guatemala, and

Yucatan. On their way back Dr. Tanquist attended the American Academy of General Practice at St. Louis, Missouri.

* * *

Dr. Louis J. Wilson, in medical practice with his father, **Dr. R. H. Wilson,** of Winona, was recalled to active duty with the United States Navy in February. Dr. Wilson received his medical degree from the University of Minnesota in June, 1952. During World War II, he served as an ensign on an aircraft carrier in the Pacific.

* * *

Dr. W. F. Widen, of the Bloomington-Lake Clinic in Minneapolis, was a recent contributor to the *Minneapolis Star* in "What My Religion Means to Me." Dr. Widen has been Sunday School superintendent at Bethlehem Baptist Church for thirty years, is chairman of the Board of Child Evangelism Fellowship for Minneapolis, director of Minneapolis Youth for Christ, winner of several national tennis honors, and was a Navy doctor in the South Pacific in World War II.

* * *

Dr. R. O. Quello, of Minneapolis, spoke to the members of the Richfield Pre-School Mothers Club on "Physical Well-Being of the Child" at the February meeting.

* * *

Dr. Glenn Nelson, of Fairfax, was appointed local chairman for the annual Heart Fund this year.

* * *

Dr. Robert B. Pierce, of Renville, barely escaped injury February 19, when his car was struck by a fast Milwaukee freight train. The car was badly damaged but Dr. Pierce had time to leap free seconds before the crash.

* * *

Dr. H. A. Christiansen, of Jackson, attended the postgraduate course on cardiovascular disease at the University of Minnesota in February.

* * *

Dr. Allan M. Gunn-Smith, recently discharged from service with the U. S. Navy, opened an office in Two Harbors in late February. He shares office space with **Dr. Ralph Papermaster** but has his own practice.

* * *

Dr. Sidney O. Hughes, recently discharged from service with the U. S. Army, joined the staff of the Winona Clinic in March. Dr. Hughes was graduated from the University of Pennsylvania Medical School in 1947. He completed his internship and a medical residency at Presbyterian Hospital in Philadelphia before being called into the army. Dr. Hughes served in Korea on the staff of the 121st Evacuation Hospital in Seoul.

* * *

Dr. Benjamin Viel, director of Chile's leading medical school, has been lecturing on health problems in Chile, at the University of Minnesota, in the absence of Dr. Gaylord Anderson, director of the school of public health, who is in Egypt.

Dr. David Hoehn, of Holdingford, was elected president of the Central Minnesota Chapter of the American Academy of General Practice, and **Dr. Bernice Andrews**, of Holdingford, was elected secretary at a meeting held in St. Cloud, February 12.

* * *

Dr. J. E. Ponterio, of Shakopee, received word of the death of his father, Angelo Ponterio, in February. Mr. Ponterio was vacationing in Sacramento, California, at the time of his death.

* * *

Dr. Barney Gervais and **Dr. Dave Sanderson**, of Fergus Falls, were among the community members named to the board of directors of the Fergus Falls Jaycees at the meeting, March 3.

* * *

Dr. Arthur C. Kerkhof, clinical assistant professor, Department of Medicine, University of Minnesota, was the guest speaker at a clinical conference on heart disease, held at the Union Hospital in New Ulm, March 5.

* * *

Dr. Owen H. Wangensteen, professor of surgery at the University of Minnesota, accented the hopeful aspect of cancer control at a Cancer campaign meeting held at the Normandy Hotel, Minneapolis, February 26 and 27.

* * *

Commander Percy Demo, son of **Dr. and Mrs. W. A. Demo**, of Blue Earth, has been assigned as physician at the American Embassy in Moscow, Russia. Commander Demo left for his assignment in late March. He will be the only American physician in Moscow, and his tour of duty is expected to extend for eighteen months. Commander Demo received his medical degree from the Iowa State Medical School. Before World War II, he practiced medicine at Wells for twelve years.

* * *

Dr. J. K. Butler, of Cloquet, attended the American Medical Association National Council on Rural Health held in Roanoke, Va., in March.

* * *

Dr. Gordon Vaughn, Saint Paul, was recently appointed National Medical Examiner for the Degree of Honor Protective Association. Dr. Vaughn is a graduate of the University of Minnesota Medical School, has had several years of general practice, and served two years in the Army Medical Corps. Dr. Vaughn is now on the staff of the Health Service at the University of Minnesota Hospitals.

* * *

Dr. Kenath Sponsel, Minneapolis orthopedic surgeon, spoke at a meeting of the Minnesota Chapter, American Physical Therapy Association, on March 4, at the Minneapolis YWCA. He described orthopedic appliances and how they can be adapted or used for physical therapy.

* * *

Dr. Albert V. Stoesser, of the Department of Pediatrics, University of Minnesota, was one of the first group of candidates to be orally examined by the new Subspecialty Board of Pediatric Allergy. The examination was given at the Children's Hospital, Harvard Medical School, Boston, on February 25, preceding the annual meeting of the American Academy of Allergy.

* * *

Dr. George E. Sherwood, of Kimball, attended the International Session of the American Academy of General Practice, held in Mexico City, April 1.

* * *

Dr. J. J. Carroll became associated with the Hartfiel Medical Clinic in the Montevideo-Maynard community in February. Dr. Carroll is a graduate of Creighton University at Omaha, Nebraska, and interned at St. Joseph's Hospital there. He spent three years in practice at Laurel, Nebraska, and was just recently discharged from the U. S. Air Force.

* * *

A contribution of $750 as a memorial to the late **Dr. Theodore Sherping** was made by the Fergus Falls Rotary Club in February. The funds were turned over to the hospital since the scholarship fund which was previously created by the Club as a Sherping memorial was seldom used.

* * *

Dr. Lyle Weed, of the Department of Bacteriology at the Mayo Clinic, spoke at the Veterans Hospital at Iowa City, Iowa, in February. Dr. Weed spoke on "Bacteriology in Modern Medicine," to doctors of the community, medical students and staff members at the University of Iowa, as well as Veterans Hospital personnel. Dr. Weed was formerly on the staff of the University of Iowa Hospital.

* * *

Dr. Louise Wurdemann, of White Bear Lake, was married to Dan Madison King, of Saint Paul, February 14. Dr. Wurdemann has been practicing in White Bear Lake since 1948. She received her medical degree from the University of Iowa and interned in East Orange General Hospital in East Orange, New Jersey. Mr. King, librarian of the Minnesota Historical Society since 1949, was formerly from New York City, and was connected with the New York Public Library and the Cooper Union for the Advancement of Science and Art.

Dr. C. R. Wall, of Minneapolis, was the guest speaker at a ladies' night banquet given by the Men's Brotherhood of the First Baptist Church at The Palms in St. Cloud. Dr. Wall, who recently returned from an extended tour of Greece, Egypt, Assam and Ethiopia, spoke on the challenge of foreign missions.

* * *

Dr. J. G. Brennan, fellow in dermatology at the Mayo Clinic, was the recipient of the first award in the third annual essay contest sponsored by the American Dermatological Association. His paper was entitled "Contributions to the Study of Pemphigus." Dr. Brennan will present his paper at the next scientific session of the Association which will be held at Lake Placid, New York, June 9 to 13.

Dr. O. K. Gilje, special student in dermatology, won honorable mention in the contest for his paper entitled "Capillary Microscopic Examination of Skin Diseases."

Dr. T. B. Fitzpatrick, former fellow in dermatology, won the award two years ago in the first annual essay contest of the Association.

HOSPITAL NEWS

St. Joseph's Hospital, Saint Paul—Minnesota's oldest hospital—will celebrate its centennial May 16 and 17.

World-famous medical persons who will be present include—Sir Alexander Fleming, British Penicillin discoverer; Dr. Philip S. Hench of the Mayo Clinic, cortisone pioneer; Dr. Richard R. Trail, British tuberculosis specialist; Dr. Louis H. Bauer, Hempstead, New York, president of the American Medical Association; Dr. Harold L. Foss of Danville, Pennsylvania, president of the American College of Surgeons, and Dr. William Boyd, pathologist of the University of British Columbia, at Vancouver.

The two-day celebration will be devoted to sessions in the Hotel Lowry and the Auditorium theater section. A centennial dinner will be held in the Hotel Lowry with reunions of interns, staff physicians, and alumnae of the nursing school. A pontifical high mass will be celebrated Sunday, May 17, in the Cathedral by Archbishop Murray.

Since St. Joseph's Hospital was founded in 1853, by the Sisters of St. Joseph, it has added a number

HOMEWOOD HOSPITAL is one of the Northwest's outstanding hospitals for the treatment of Nervous Disorders—equipped with all the essentials for rendering high-grade service to patient and physician.

Operated in Connection with
Glenwood Hills Hospitals

of historic "firsts" in its field. The first successful removal of a gall bladder in America was done there in 1886 by Dr. Justus Ohage; in 1903, probably the nation's first real use of a bronchoscope was made by Dr. Arnold Schwyzer. Recently the hospital has taken the lead by being the first private hospital to do chest x-rays on all patients routinely on admission.

* * *

A new research laboratory at *Ancker Hospital,* Saint Paul, is nearing completion. It is a small red brick building which houses a chemistry laboratory, an operating room for experimental surgery, a post-surgical recovery room, animal rooms and research workrooms. It is air-conditioned to prevent summer deaths of research animals. Most of the ceilings are unplastered because plastering is expensive, but the walls are tiled. The building is windowless with a modern hood in the chemistry laboratory to draw away dangerous fumes. All planning has benefited from the services of the same architect who designed the Mayo Clinic and Mayo Foundation's new four million dollar medical sciences building.

Construction was planned so additions are possible, as Dr. Ivan Baronofsky plans some day to see a radioisotope laboratory for work with atomic medicines added to the present building.

Dr. Baronofsky, University of Minnesota staff member, director of postgraduate surgical education at Ancker Hospital, is largely responsible for the existence of the new laboratory. When he was told that welfare funds would not be made available for such a laboratory, he managed to recruit some $74,000 in private donations to the Minnesota Medical Foundation. Over the next two years the welfare board added $60,000, thus making the building of the lab possible.

The United States Public Health Service, the Minnesota Heart Association, and the University of Minnesota graduate school have made research grants.

* * *

On January 18, 1953, the new **Hudson Memorial Hospital** was formally opened. The event culminates seven years of planning and demonstrates what persistence on the part of a small community can accomplish.

The community of 3,500 persons at Hudson, Wisconsin, has been in need of a first class hospital for years. The donation, in 1946 of $70,000 by Mr. and Mrs. Stephen C. Phipps of Hudson, in memory of Mr. Phipps' father started the project. Mr. and Mrs. Charles A. Ward, also residents of Hudson, added $50,000 which with $30,000 contributed by the Trustees of the Dr. Boyd Williams Estate Trust and $40,000 by the town of Hudson was supplanted by individual donations from some 900 families to attain the goal of $469,000. The hospital auxiliary, with 500 members, sponsored teas and card parties and prepared the linen and gowns. Volunteers helped clear the ground and police the hospital for the grand opening. As a result of community cooperation, the hospital is debt-free and has a fund of $20,000 to start operation. No government funds were requested or received.

THEOCALCIN

Theocalcin

For the Failing Heart of Middle Life

Prescribe 2 or 3 tablets of Theocalcin, t. i. d. After relief is obtained, continue with smaller doses to keep the patient comfortable. Theocalcin strengthens heart action, diminishes dyspnea and reduces edema.

Brand of theobromine-calcium salicylate,
Trade Mark reg. U. S. Pat. Off.

Bilhuber-Knoll Corp. Orange, N. J.

The Hudson Memorial Hospital has eight private and twelve semi-private rooms, all with picture windows overlooking the St. Croix valley. The hospital is complete with a central oxygen supply piped to each room, a delivery room equipped with an oxygen-air pressure lock, a device for inducing natural breathing in newborn infants, modern laboratories and an out-patient department.

The inhabitants of Hudson are to be congratulated on their community spirit.

* * *

Dr. R. H. Moe was elected the new chief of staff of St. Mary's Hospital, Duluth, and Dr. F. T. Becker, the new acting chief. Dr. G. C. McRae was chosen chief-of-staff-elect, and Dr. J. D. Barker, secretary.

Departmental chiefs named for two-year terms were Dr. J. S. Spang, surgery; Dr. R. O. Bergan, pediatrics and contagion; Dr. J. E. Haavik, neuropsychiatry; Dr. J. F. Schmid, dermatology, and Dr. J. F. Feuling, physical medicine.

* * *

Dr. Nordahl P. Peterson was named the chief of *Swedish Hospital* medical staff for 1953, with Dr. Leonard S. Arling, vice president, and Dr. Elmer T. Cedar, secretary-treasurer, at the regular meeting in March. The executive committee includes Dr. Russell C. Lindgren, Dr. Robert E. Johnson, Dr. Arthur N. Russeth and Dr. V. J. P. Lundquist.

* * *

Dr. Henry C. Goss was elected chief of staff at the *Glencoe Municipal Hospital* at the annual meeting held in March. Dr. C. W. Truesdale was named secretary-treasurer.

BLUE CROSS-BLUE SHIELD NEWS

During the approximate five years that Blue Shield has been operating, it has shown a continued growth in enrollment. In the earlier development of Blue Cross and Blue Shield, the need was experienced for swift mass enrollment, and in addition this was felt to be the soundest method of securing subscribers. After several years, complaints were voiced by self-employed persons and those who were unable to secure coverage through a group. This was particularly true in the rural areas of Minnesota, and it became apparent that employed people of urban areas enjoyed a distinct advantage. Thus, with some misgivings, the first non-group campaign was initiated with only one effective date per year. The actuarial soundness of non-group enrollment, based on critical screening of the applications to eliminate undesirable risks, became immediately apparent so that the program was expanded to three or four enrollment dates a year. In keeping with this program of covering more people and increased benefits, the Board of Directors has approved a policy for continuous non-group enrollment offering to every eligible person the opportunity to participate in the plan without the necessity of waiting for infrequent or periodic enrollment dates. This represents another significant milestone in the long-range program of providing the maximum in medical and surgical benefits to the greatest number of people at a cost which they can afford.

The benefit increases which went into effect on October 1, 1952, are now beginning to be reflected in the monthly Blue Shield claims payments for services rendered by doctors of medicine. On the basis of the present enrollment in Blue Shield with its increased benefits, analysis shows that payments to doctors for services rendered will exceed four and one-half million dollars in 1953. With the growing demand of the public to be adequately protected in the field of medical and surgical care, the foregoing facts clearly indicate that Blue Shield by increasing its benefits and coverage is providing the solution for financial burdens involved in maintaining and increasing health standards. Such expansion is part of a long-range program to make the "Doctors Plan" the foremost method in the nation for the relief of the public from the financial hazards involved in the preservation of health.

Such a program requires the constant co-operation of the members of the medical profession as well as their knowing what Blue Shield provides, what it does not cover, and whenever possible their securing new subscribers for the plan. To aid in the administration of this year-around continuous non-group enrollment policy, new non-group applications are now being prepared, and with them, the mechanics of enrollment are simple. The applicant must be under sixty-five years of age,

give a small amount of medical history and mail the application to the Blue Shield office. Review of the medical history is being revised so that as few riders or exclusions as possible will be issued in conjunction with these contracts.

In establishing this program, complete analysis has been made of similar enrollment programs carried on by other Blue Shield plans in the nation. Every method has been made to utilize the best features of those plans which have been successful in promoting such a program, and to eliminate insofar as possible any restrictions upon enrollment. For actuarial soundness, some limitations or enumeration of those things which Blue Shield does not cover, are essential. Only in this manner, will the plan be financially secure for its participating subscribers regardless of epidemics or catastrophic emergencies. A successful non-group enrollment campaign carried on by Blue Shield with the co-operation of its participating physicians will assist materially in the further growth of the plan, and will provide the proper security for unlimited future development and expansion toward the goal of complete solution of the socio-economic problem involved in providing the best in high-grade medical and surgical care.

MEDINA CRITICIZES SEARCH FOR SECURITY

Federal Judge Harold R. Medina, of New York, said that "everyone seems to be looking for security." Boys just out of college ask personnel directors what the pension rights are and at what age they will be allowed to retire, he said at the summer commencement exercises of the University of Chattanooga. "Croakers abound everywhere telling us that everything is going to pot, that the world is plumb full of corruption, and that nothing can be done about it.

"But the truth is that this do-nothing policy of playing everything safe is just about the worst thing that a person can do."

Turning to the Scriptural parable of the talents, in which those who traded and thus increased the number of their talents were commended while one who hid his talent in the earth was reproved, Judge Medina said that he believed this was a lesson "telling us, don't be afraid, don't be cynical, don't be lazy, keep plugging away all the time with zest and enthusiasm." The talent was both an ancient weight and unit of money.—*New York Times*, Sept. 3, 1952.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

RYPINS' MEDICAL LICENSURE EXAMINATIONS. Topical Summaries and Questions. Seventh Edition. Walter L. Bierring, M.D., F.A.C.P., M.R.C.P. Edin. (Hon.). Former Member, National Board of Medical Examiners, American Board of Internal Medicine, Iowa State Board of Medical Examiners; Professor Emeritus Theory and Practice of Medicine, College of Medicine, State University of Iowa; Secretary Federation of State Medical Boards of the United States; Chairman, American Board of Preventive Medicine and Public Health; Iowa State Commissioner of Health. With collaboration of a Review Panel. 856 pages. Price $8.00, cloth. Philadelphia: J. B. Lippincott Co., 1952.

CLINICAL APPLICATIONS OF SUGGESTION AND HYPNOSIS. Second Edition. William T. Heron, M.A., Ph.D., Professor of Psychology, University of Minnesota, Minneapolis, Minnesota. 137 pages. Price $3.75, cloth. Springfield, Illinois: Charles C Thomas, 1953.

DOCTOR IN THE HOUSE. Richard Gordon, 186 pages. Price $2.75, cloth. New York: Harcourt, Brace & Co., New York, 1953.

CHILD DEVELOPMENT. The Process of Growing Up in Society. William E. Martin and Celia Burns Stendler, of the University of Illinois. Under the editorship of Willard B. Spalding, Oregon State System of Higher Education. 519 pages. Illus. Price $6.50, cloth. New York: Harcourt, Brace & Co., New York, 1953.

CLINICAL ALLERGY. French K. Hansel, Director, Hansel Foundation for Education and Research in Allergy; Chief of Allergy Service, DePaul Hospital, St. Louis. 1005 pages. Illus. Price $17.50. St. Louis, C. V. Mosby Co., 1953.

This book was written to replace Dr. Hansel's limited text on *Allergy of the Nose and Paranasal Sinuses* (1936). Because of the great advances in the knowledge of allergy, the earlier text is no longer adequate today.

The author has written this for anyone interested in the subject. It is for the specialist, for the general practioner, and for the beginner in allergy.

In the first chapter, terminology is discussed so that there will be no confusion as to meaning of terms; and included is a revised list of definitions, prepared by the Committee on Nomenclature of the Association of Allergy Clinics of Greater New York, and a historical review of the field of allergy.

Dr. Hansel presents his subject by giving first the basic concepts of anaphylaxis and allergy. Then he describes the different types of allergies, such as serum allergy, allergic reactions to insects, hay fever due to pollens. Diagnosing allergies requires careful history taking and testing. For the latter, the author lists supplies needed, explains how to prepare dilutions, and outlines the technique of giving tests, and discusses the interpretation of reactions.

A large section of the book is devoted to discussion of the manifestations and treatment of allergy from the standpoint of organs and system involved; and five chapters are given over to allergy in children. The bibliography at the end of each chapter contains numerous and up-to-date references.

M.M.P.

OFFICE MANAGEMENT OF OCULAR DISEASES. By William F. Hughes, Jr., M.D., Professor and Head, Department of Ophthalmology, University of Illinois College of Medicine; Ophthalmologist in Chief, Illinois Eye and Ear Infirmary, and Attending Ophthalmologist, Presbyterian Hospital, Chicago. 452 pages. Illus. Price $9.00. Chicago: Year Book Publishers, ©1953.

"Office management of ocular diseases" is a well-planned, well-written summary of the diagnosis and treatment of diseases commonly encountered in ophthalmological practice. The author is particularly well qualified because of his special interest and past contributions to the literature in the field of beta radiation therapy, corneal burns and plastic surgery of the lids; and in these fields the book is particularly excellent. The chapter on Radiation treatment of the eye contains basic information presented in a form which is readable and understandable. It could be read with profit by every ophthalmologist even though this therapy is usually carried out in collaboration with a radiologist.

The book contains up-to-date information on all new drugs and procedures. For example, the indications for the use of cortisone are extensively outlined; and the techniques of measurement of rate of aqueous outflow (tonography) and of application of beta rays to the cornea are detailed.

A general practitioner could have no better reference book in emergency office treatment of eye diseases and minor eye and lid surgery he may be called upon to perform. The short but adequate summaries of neuro-ophthalmology, and diseases of the conjunctiva, cornea and orbit would be invaluable to him. The taking of visual fields, modern treatment of cataracts and glaucoma and problems of ocular motility are treated with enough basic information to give the general practitioner an understanding of the ophthalmologist's treatment. Indeed, the only criticism of the book, and it is a forgivable one, is that quite extensive passages would be elementary for the average opthalmologist and seem better designed for a non-specialist or student.

J. A. McNeill, M.D.

SECOND ANNUAL REPORT ON STRESS. Hans Selye, M.D., Ph.D. (Prague), D.Sc. (McGill), F.R.S. (Canada), Professor and Director of the Institut de Médecine et de Chirurgie expérimentales, Université de Montréal, and Alexander Horava, M.D. (Lausanne), Research Associate and Librarian of the Institut de Médecine et de Chirurgie expérimentales, Université de Montreal. 526 pages. Illus. Cost $10.00. Montreal: Acta, Inc., ©1952.

This volume is the second of a series of annual supplements to the book, *Stress—The Physiology and Pathology of Exposure to Stress,* by Hans Selye. According to the introduction (p. 1), these annual reports are "written as a combination of an extensive classified index of pertinent new facts (literature and unpublished observations made at our Institute during the year) with a concise evaluation of the principal findings." That such a compilation is a task is evidenced by the fact that in this volume alone references are made to over 4,000 publications.

Before attempting to use this volume, one is urged to study the introduction which explains how to use the annual report to best advantage. The report contains a "brief synopsis of the stress concept as it presents itself in 1952," the fourteen principal criticisms of the concept, and the problems to be solved. It also contains a classified index to the references covering both general and special physiology and pathology of stress with introductory notes. There is a series of photographs showing recent observations on the effects of stress and the adaptive hormones. The bibliography itself is arranged alphabetically by author; and for quick reference there is an alphabetical subject index at the end.

M.M.P.

MEDICAL MANAGEMENT OF GASTROINTESTINAL DISORDERS. Garnett Cheney, M.D., Clinical Professor of Medicine, Stanford University Medical School. 478 pages. Illus. Price, $6.75. Chicago: The Year Book Publishers, 1950.

This very readable book is divided into two parts. The first part is called "The Patient Approach" and deals with the all-important history and physical examination. Clinical laboratory examinations are dealt with in turn, followed by the indications for special endoscopic and x-ray examinations.

The second half of the book deals with gastrointestinal disorders from the point of view of symptomatology instead of the more orthodox method of presenting diagnoses. This method makes the book a handy reference source for the practitioner or student.

The author presents a concise, common sense approach to the medical management of Gastroenterology. Psychogenic and somatic aspects are presented in sound perspective.

The book is of interest to the internist and should be of particular value to the student and general practitioner.

Dwight L. Martin, M.D.

TEXTBOOK OF SURGERY. Edited by H. F. Moseley, M.A., D.M., M.Ch. (Oxon), F.A.C.S., F.R.C.S. (Eng.), F.R.C.S. (C.), Assistant Professor of Surgery, McGill University; Associate Surgeon, Royal Victoria Hospital, Montreal, Canada. Foreword by G. Gavin Miller, M.D., C.M., M.Sc., F.R.C.S. (C.), F.A.C.S., Chairman of the Surgical Department, McGill University; Surgeon-in-Chief, Royal Victoria Hospital, Montreal, Canada. 896 pages. Illus. Price, $15. St. Louis: C. V. Mosby Co., 1952.

This unusually good textbook of surgery is edited by an assistant professor of surgery at McGill University. The organization and presentation of material makes it a fine text for the student and intern as well as a good reference work for the physician. Of particular note is the use made of illustrations throughout the text. Forty-six color plates, most of which were produced by Frank Netter, serve as potent visual aids to the well-organized text. In addition to these plates, there are 460 figures consisting of clear reproductions of roentgenograms, lucid diagrams and good photographs to illustrate the text. It is the intelligent use of these plates and figures which make this book stand out among the rank and file of surgical texts. For example, many pages could not describe what Netter has conveyed in four color plates dealing with the diseases of the prostate gland.

The text has been carefully considered and finely written. Its brevity is commendable. Discussion of diseases and pathologic conditions is succinct but adequate while the presentation of methods of treatment is complete and thoroughly up to date.

The chapter on the heart and pericardium contains much about congenital cardiac lesions, cardiac arrest, and acquired cardiac lesions not found in other texts of surgery. The treatment of these lesions is presented in a manner which makes it simple for the student to understand the principles of the operations.

In general, the chapter on thoracic surgery is good. However, the changes in the field of surgery of pulmonary tuberculosis have been so rapid that this section is already somewhat outdated. Mention is made of resectional surgery for pulmonary tuberculosis, but too little space is given this method of therapy, while too much space is allotted to thoracoplasty.

On the whole the book can be recommended as one of the best textbooks of surgery to date. Certainly it is a text which will allow the medical students to more simply and quickly cover the broad field of surgery. It is pleasant to find a book which offers sensible short cuts to understanding at the present time, when we are so prone to overwhelm the reader with verbosity.

Frederich M. Owens, Jr., M.D.

PHYSICIANS' COLLECTIONS SHOW SLIGHT DECLINE

The average United States physician collected 85 per cent of the bills owed him by patients last year—a decline of three percentage points in his rate of collections since 1948.

So states the March issue of *Medical Economics,* national business magazine for doctors, which is publishing the results of a nationwide survey of medical practice, based on a questionnaire sent to each of its 134,000 physician-readers.

The magazine also found that the average doctor nowadays takes in $2,601 a year from Blue Shield and other health plans. This amounts to about 11 per cent of his gross income.

MEAD JOHNSON & COMPANY
Evansville 21, Ind., U. S. A.

dvertisements addressed to the general public . . .

hysician, you're in *good* hands"

eglect . . . delay. How many times, doctor, have you ared for patients . . . whose hope of recovery might ave been bright indeed . . . *but for neglect or delay in eeking your help?*

Undoubtedly, this occurs so often . . . and usually with ich tragic consequences . . . that many physicians view as the greatest problem facing medical science today.

Moreover, this problem may assume even greater gnificance with the rising incidence of the degenera- ve diseases. For in these conditions, neglect and delay, s you well know, are *directly* responsible for a heavy ll of life.

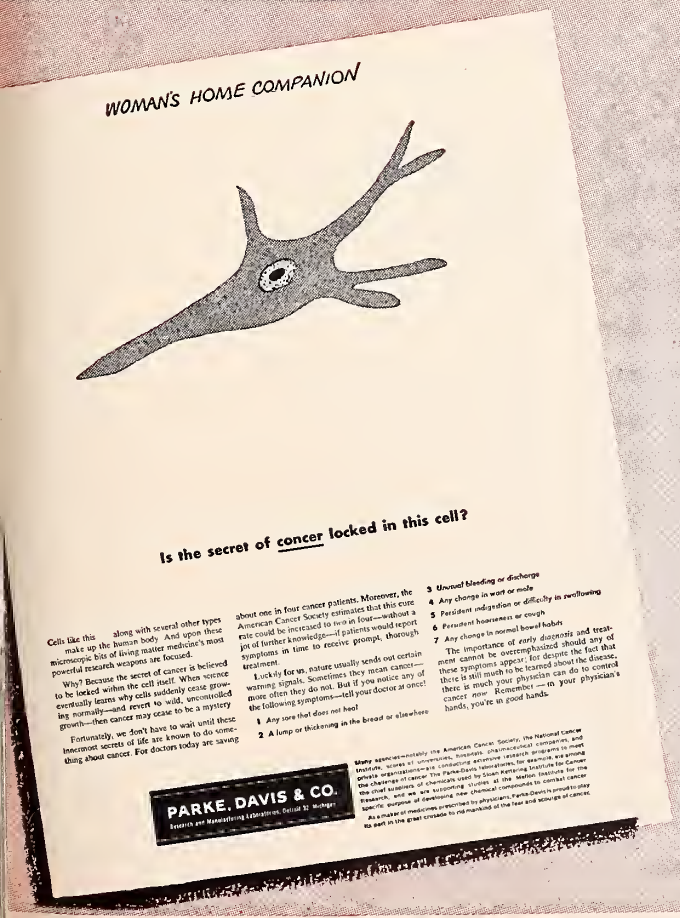
We believe you will agree that this problem deserves icreased and continuing emphasis. This is why Parke- avis will publish, throughout 1953, a series of adver- sements on the *patient's responsibility* in medical care.

These advertisements, four of which are reproduced ere, will appear in leading magazines reaching mil- ons of families. In them, this central theme will be mphasized:

That every individual, if he wants his physician's most effective help, must meet the doctor halfway. *He must not ignore symptoms, or delay treatment. He must act promptly . . . and be made to realize that "in the hands of your physician, you're in* good *hands."*

In addition, the advertisements will stress the fact that medicine has a vast store of new knowledge . . . and that this knowledge is constantly increasing through research by physicians, hospitals, public and private health organizations, and pharmaceutical companies.

A word about the preparation of these advertisements: They have been carefully written to avoid both the possibility of stimulating hypochondria and encouraging self-diagnosis. Equally important, the advertisements make no claims that might cause undue optimism or raise false hopes. We believe these are just the type of informative messages you will want your patients to read. Our efforts will be guided and encouraged by your continued interest and comments.



WOMAN'S HOME COMPANION

Is the secret of cancer locked in this cell?

Cells like this along with several other types make up the human body. And upon these microscopic bits of living matter medicine's most powerful research weapons are focused.

Why? Because the secret of cancer is believed to be locked within the cell itself. When science eventually learns why cells suddenly cease growing normally—and revert to wild, uncontrolled growth—then cancer may cease to be a mystery.

Fortunately, we don't have to wait until these innermost secrets of life are known to do something about cancer. For doctors today are saving about one in four cancer patients. Moreover, the American Cancer Society estimates that this cure rate could be increased to two in four—without a jot of further knowledge—if patients would report symptoms in time to receive prompt, thorough treatment.

Luckily for us, nature usually sends out certain warning signals. Sometimes they mean cancer—more often they do not. But if you notice any of the following symptoms—tell your doctor at once!

1 *Any sore that does not heal*
2 *A lump or thickening in the breast or elsewhere*
3 *Unusual bleeding or discharge*
4 *Any change in wart or mole*
5 *Persistent indigestion or difficulty in swallowing*
6 *Persistent hoarseness or cough*
7 *Any change in normal bowel habits*

The importance of *early diagnosis* and treatment cannot be overemphasized should any of these symptoms appear; for despite the fact that there is still much to be learned about the disease, there is much your physician can do to control cancer *now*. Remember—in your physician's hands, you're in *good* hands.

PARKE, DAVIS & CO.
Research and Manufacturing Laboratories, Detroit 32, Michigan

Many agencies—notably the American Cancer Society, the National Cancer Institute, scores of universities, hospitals, pharmaceutical companies, and private organizations—are conducting extensive research programs to meet the challenge of cancer. The Parke-Davis laboratories, for example, are among the chief suppliers of chemicals used by Sloan Kettering Institute for Cancer Research, and we are supporting studies at the Mellon Institute for the specific purpose of developing new chemical compounds to combat cancer.

As a maker of medicines prescribed by physicians, Parke-Davis is proud to play its part in the great crusade to rid mankind of the fear and scourge of cancer.

IN SPRING ALLERGIES . . .

Allay Distress

Patients suffering from Spring allergies can be relieved promptly of annoying symptoms—with NEO-ANTERGAN.

NEO-ANTERGAN effectively blocks the tissue histamine receptors, affording quick comfort with a minimum of sedation or other undesirable effects.

Promoted exclusively to the profession, NEO-ANTERGAN is available only on your prescription.

Your local pharmacy stocks NEO-ANTERGAN Maleate in 25 and 50 mg. coated tablets in bottles of 100, 500, and 1,000.

Meat...

and the Low Sodium Diet

The beneficial effect of sodium restriction in the management of hypertension and many types of cardiac disease is firmly established. A low sodium diet aids in preventing edema and frequently leads to a significant reduction in arterial tension.

To emphasize the importance of sodium restriction and to enable the physician to present his patient with an informative discussion of the subject, The American Heart Association has just published a valuable pamphlet entitled "Food For Your Heart."* Covered also in this booklet is the importance of weight reduction in the management of the cardiac patient.

Dietary recommendations for three levels of sodium restriction are given. In all of them, meat is an important constituent of the diet. In the diet providing moderate sodium restriction (0.5 to 1.5 Gm. of sodium), 4 to 6 ounces of unsalted meat, fish or fowl are allowed. In severe restriction (0.5 Gm. sodium), 3 to 4 ounces of meat are permitted daily. The weight reduction-moderate sodium restriction diet calls for 5 to 6 ounces of meat daily.

This booklet again emphasizes the valuable application of meat in the dietary management of cardiac disease, hypertension, and obesity. Since, as the manual emphasizes, infectious diseases and such scourges as typhoid fever have now been controlled with antibiotics, chemotherapeutic agents and modern sanitation, "many physicians and scientists consider nutrition the most important environmental factor in health."

Meat, with its wealth of high quality protein, B complex vitamins and important minerals, plays an important role in the aim toward better national health. That the generous consumption of meat by the American people is a significant factor in attaining this goal is reflected in the statement that "most physicians feel that the high American consumption of protein is a good thing."

HAVE you tested the new degrees of effectiveness and acceptability provided by SULESTREX?

Results are prompt, constant, and predictable . . . "*with an amazingly low incidence of side reactions.*"[1] Regardless of the intensity of treatment, there is no possibility of esthetic "embarrassment."

Measure these advantages when prescribing for your next menopausal patient. SULESTREX (piperazine estrone sulfate, Abbott) provides the natural estrogen, estrone, in pure crystalline form. It is not a mixture of estrogenic agents of variable potencies. SULESTREX is stable, water-soluble, odorless and tasteless.

You may choose from three prescribing forms: Tablets,* Sub-U-Tabs,** and Elixir.* Try it soon, with this confidence: you can't prescribe a more effective oral estrogen.

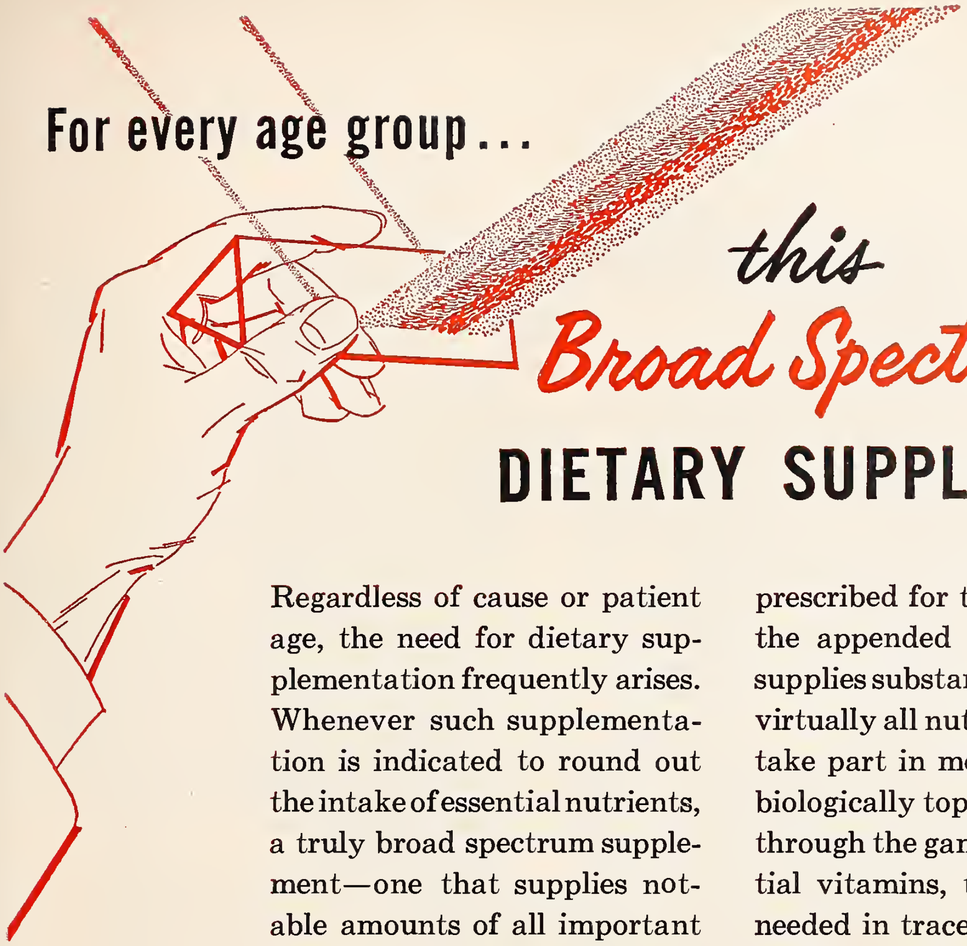
For every age group...



this *Broad Spectrum* DIETARY SUPPLEMENT

Regardless of cause or patient age, the need for dietary supplementation frequently arises. Whenever such supplementation is indicated to round out the intake of essential nutrients, a truly broad spectrum supplement—one that supplies notable amounts of all important nutrients—will serve the patient optimally.

Ovaltine in milk, a delicious food drink, has long been widely prescribed for this purpose. As the appended table shows, it supplies substantial amounts of virtually all nutrients known to take part in metabolism, from biologically top-grade proteins, through the gamut of the essential vitamins, to the minerals needed in trace amounts.

Whenever the patient's nutritional state must be improved, Ovaltine deserves the physician's first consideration.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

CIVIL DEFENSE: A REPORT TO THE MEMBERSHIP

JAN H. TILLISCH, M.D.
Rochester, Minnesota
and
JOHN T. SMILEY, M.D.
Minneapolis, Minnesota

CIVIL defense is like virtue—everyone is for it but comparatively few people do much about it. Yet civil defense is a highly personal necessity. In any type of disaster, you, your family or your community may be involved.

The need for civil defense is apparent with the negation of our natural geographic defenses by intercontinental bombers and guided missiles. This means that whether we are engaged in a hot war, a cold war or no war, we can no longer depend on oceans for protection; thus, a scheme must be evolved for civil defense that will be effective and long standing. Adequate civil defense offers a chance for survival but also acts as a deterrent to the enemy. One of the factors that led Hitler to decide against invasion of England was the well-co-ordinated program of civil defense present in Great Britain.

More specifically, the need for civil defense is evident in view of the weapons now available. The atomic bomb is the most imposing of the new array of weapons, and many civil-defense activities have been pointed toward defense against and survival of disasters caused by atomic bombs. However, this country should not prepare for one emergency to the exclusion of all others. High-explosive bombing in World War II reached a new and appalling degree of efficiency. Chemical warfare is a threat that assumes terrifying proportions with the realization that chemical weapons can be delivered by plane or guided missile into the midst of an unsuspecting and unprepared people. This is also true of bacteriologic warfare, a method as yet untried. Finally, the actual invasion of the United States by enemy troops is a possibility that cannot be ignored. Thus, it can be seen that many aspects are present in civil defense, but one recurrent need appears in all, namely, the requirement of a medical program.

Less horrifying than the possibilities just mentioned but more likely to occur is a local storm, fire or flood of such magnitude that local facilities cannot cope with it. Such possibilities constitute an ever-present problem and emphasize the need for not only an efficient and well-co-ordinated medical program for use in time of war but also placement of such a program on a permanent basis.

The Minnesota Civil Defense Law

In Minnesota, civil defense has been recognized by law as a governmental responsibility. In 1951, the legislature established the Civil Defense Advisory Council and appropriated funds for the organization and operation of a permanent State Department of Civil Defense. The same law stated that every municipality must appoint a director of civil defense and create a civil-defense organization. It authorized the levying of taxes to finance community work in civil defense.

The director of the Minnesota Department of Civil Defense is Colonel E. B. Miller, who was appointed by the governor. Permanent headquarters have been established at 1643 Rice Street, St. Paul 3, Minnesota. Regional offices have been established in St. Paul, North Mankato, St. Cloud, Bemidji and Hibbing.

Dr. Tillisch is chairman of the Committee on Military Affairs, Minnesota State Medical Association.

Dr. Smiley is Director, Office of Health Service and Special Weapons Defense, Minnesota Department of Civil Defense.

The State Department of Civil Defense is a coordinating agency in predisaster planning; it would have a supporting role should an attack occur. The operating cost of the State Department of Civil Defense is borne by the state without help from the federal government. Likewise the operating cost of departments of civil defense in cities and villages must be paid by the local community. From federal sources, $450,000 was allocated to Minnesota for the purchase of medical supplies and equipment to be stockpiled for possible future use. However, these funds were made available only when they were matched dollar for dollar by the state or by its component municipalities. No outright grants have been made to Minnesota or any other state for purposes of civil defense.

From an appropriation made in 1951 by the legislature to purchase organizational equipment for civil-defense units, $10,000 has been used to match federal money in the purchase of medical supplies. This was spent to equip twenty teams manning mobile first-aid stations. The three largest cities in the state have matched collectively slightly less than $7,000 for medical supplies. It should be clearly understood that the civil-defense plan in Minnesota does not include requests for huge sums of money. It is based on the belief that existing local resources should be used, supplemented only by the acquisition of equipment and supplies peculiar to civil-defense operation and not normally available.

The Medical Civil Defense Plan

Through the Civil Defense Medical Advisory Committee, the Minnesota State Medical Association was given a definite responsibility for the initiation of medical civil-defense plans. The Committee on Military Affairs was in turn designated to work with the Minnesota Department of Health and with a committee of the Minnesota Hospital Association in the development of detailed plans. In its approach to the problem of creation of a really practical, long-term, simple plan for statewide application, this group decided to set up a single hypothetic situation and then to develop a scheme to meet it. The hypothetic situation was a simultaneous attack with atomic bombs on the Twin Cities and Duluth.

Emergency medical care apparently was the most urgent and difficult problem, so this was tackled first. This emergency medical care divided itself naturally into four categories as follows:

1. Self-help—assistance given to its injured by the stricken community itself.
2. Mutual aid—assistance given to the injured of a stricken community by other communities immediately adjacent to it.
3. Mobile support—assistance given to the injured of a stricken community by teams brought under state control from outlying communities.
4. Fixed support—assistance given to the injured of a stricken community by an outlying community that receives them into its own home facilities.

Beginning with the last of the four categories, a plan was prepared called "The Support of the Twin Cities and Duluth in the Emergency Medical Care Phase of Civil Defense." This plan was designed to provide a pattern of operation for the whole state in the fixed-support portion of the operation. It designated seventy-eight communities as the points at which definitive hospitalization and medical care are to be provided. It also directed that these communities be organized to receive an overwhelming number of medical evacuees. It prescribed routes of evacuation from the areas of disaster and asked that each community organize a team to control traffic. It prescribed in a general way the medical responsibilities of each region in the state. This plan was approved by the Civil Defense Advisory Council on February 24, 1952. Copies have been sent to every member of the Minnesota State Medical Association.

At the same time, the Council approved the outline of a plan to deal with the mobile-support portion of the operation. On September 1, 1952, that plan was launched. It provided for the organization of the previously mentioned twenty mobile first-aid teams that could be rushed to the periphery of a region of disaster to support local facilities. The communities selected as sites for the organization of these teams are:

1. Stillwater
2. Red Wing
3. Northfield
4. Owatonna
5. St. Peter
6. Hutchinson
7. Anoka
8. Buffalo

The equipment for these teams has been ordered and has begun to arrive at the State Training School in Red Wing, where it is to be sorted, repacked and stored temporarily. It was purchased with the combination of federal and state funds previously referred to. The civil-defense directors of the designated communities must select the captains of the teams, who are to be physicians, and must take the initiative in the organization of the team in each community. Selection of the sites for the locations of teams has been influenced by the probability that the Twin Cities and Duluth will be the most likely targets and will have the most acute needs. The plan assumes, however, that these teams providing medical care will be available to go to the support of any community in Minnesota that suffers a disaster with which it cannot cope. The same is true of the plan for fixed support. It is necessary only to rearrange the routes of evacuation to produce a plan for the support of any community in the state.

Additional plans must be developed. At present some ideas are being discussed regarding the creation of agreements for mutual aid. Other phases of medical operations in civil defense include the following: (1) ordinary medical care of the populace in regions removed from disaster; (2) medical care and hospitalization in refugee camps; (3) medical care of civil-defense forces; (4) treatment and handling of casualties of chemical attack and (5) detection of radioactivity and handling and treatment of persons contaminated with radioactive materials.

All these factors must be considered in the light of conditions imposed by the hypothetic disaster, and plans must be developed to cover these eventualities as far as possible within the limitations of probable resources of the state and the ability of the committees to see clearly the problems to be expected.

Role of the Individual Physician

The importance of the physician in state civil defense is apparent from the plans mentioned. The physician's place in the community and his responsibility for the care of his fellow man makes it necessary for him to give the program full support. It appears likely that every able-bodied physician in civilian practice in the state can expect to be asked to take part in civil defense, in either a key position or a supporting role. Even if the physician is not called on now for active participation in the program of preparedness, he should realize that he is part of the reserve that may be called on to put these plans into action. Therefore, all physicians in the state should be informed about and interested in all phases of civil defense. They should respond promptly and cheerfully to requests for counsel and for active participation in the civil-defense activities in their community.

The physician can aid in civil defense in other ways because of his position as a leader and medical adviser in his community. The first-aid program of the American Red Cross should be encouraged and given all possible support. This applies most strongly to recruitment of donors for the blood program. Education of the community in regard to the medical aspects of civil defense is a physician's responsibility. This may be discharged through individual discussion with local citizens or talks to various organizations. The physician should keep informed about latest developments in the medical aspects of civil defense by reading and by attendance at medical meetings. By such methods, we, the physicians who form the keystone of civil defense, can give effective support to this important matter.

WHAT CAN YOU GIVE AWAY, BUT STILL HAVE?

The answer is *Blood*! You can donate a pint to the National Blood Program but still have all your blood . . . because your body makes more to take its place.

As an average healthy person, you have twelve to thirteen pints of blood. Your blood is constantly being replenished. The removal of a pint calls for no special effort on the body's part. The liquid part is replaced almost immediately, the cells and minerals after a few days. Donating a pint of blood is comparable to an afternoon's exercise. A person in good health can do either safely.

So, you can give . . . again and again . . . actually to gain back every drop. When you donate a pint of blood, the only feeling you have is one of satisfaction in helping someone live.

To meet the nation's need for whole blood and derivatives, the National Blood Program must receive the voluntary donation of over 5,000,000 pints this year. To Federal Civil Defense for building reserves of serum albumin, to accident victims in need of whole blood transfusions, to wounded service men in need of shock units of serum albumin, and to children exposed to polio in need of the blood derivative Gamma Globulin, *your blood is vital.*

Your donation means so much and costs you absolutely nothing. Your blood spells life and health to so many without your really losing a thing. Call your local Red Cross, Community or Armed Forces Blood Donor Center today and schedule YOUR donation.

BRUCELLOSIS IN MAN

A Study of Thirty-five Cases Due to Brucella Abortus

WENDELL H. HALL, M.D., Ph.D.
Minneapolis, Minnesota

THE CLINICAL course of human brucellosis has been well defined by Hughes,[12] Eyre[5] and others. With few exceptions, these reports have been based upon studies of patients infected with *Brucella melitensis*. The course of human infections due to *Br. suis* has been clearly described by Jordan and Borts.[13] This paper summarizes our experiences at the Minneapolis Veterans Administration Hospital with thirty-five patients having brucellosis proved by culture to be caused by *Br. abortus*. Epidemiologic, diagnostic and therapeutic observations are emphasized.

Material

The patients were all hospitalized. An unusual opportunity was afforded us to observe the progress of these patients. They have been reexamined in the hospital at intervals of one to six months for as long as six years. They were all males and their ages ranged from twenty-one to fifty-nine years (mean = 35.7 years). These patients came from the upper Midwest, principally from Minnesota and Wisconsin. This region possesses several large meat packing plants, but the area is largely agricultural with emphasis upon dairy cattle. Thirteen patients were farmers who owned cows with contagious abortion or Bang's disease. Fifteen patients were packing plant employes; four worked on beef kill, eight on hog kill and three were not exposed to fresh meat. There was one veterinarian. Six patients had no direct animal contacts, but five of these consumed unpasteurized milk or cheese and one often repaired radios covered with manure.

We were able to examine the families of five of the patients who lived on farms. Only two of the fifteen related people were ill, yet six had Brucella agglutinins in their serum. One fifteen-year-old girl, who had no recognizable illness, was found to have an agglutinin titer of 1:160 and *Br. abortus* was isolated from her blood. Most of these people had little contact with animals but were drinking unpasteurized milk from infected cattle.

Methods of Study

All thirty-five patients were admitted to the hospital and examined carefully by the usual clinical and laboratory methods. None of them had received Brucella vaccine or skin tests prior to examination nor were they used by us.

Brucella Agglutinins.—We have frequently employed Castaneda's rapid slide or "spot" test[3] for the quick detection of patients having brucellosis and have found it useful in the presence of active infection.[7] However, in all instances we have found it advisable to measure the titer of agglutinins by the tube dilution method of Fitch.[6] Incubation was carried out for twenty-four hours at 37° C. The antigen was heat-killed *Br. abortus* supplied by the Bureau of Animal Industry, U. S. Department of Agriculture, Beltsville, Maryland.

The Brucella opsonocytophagic index, precipitin test and complement-fixation tests were not used routinely. The tube-dilution agglutinin test has proved simpler, safe and more reliable. The results of comparative studies with other agglutinin methods have been published elsewhere.[7]

Cultures for Brucella.—At least three blood cultures were obtained from each patient before chemotherapy was started. Cultures of sternal bone marrow were frequently obtained as well as histologic sections of the marrow units in a search for granulomas.[23] The Castaneda[4] double medium culture bottle was used throughout this study. We employed a 100 ml. "French square" bottle closed with a rubber diaphragm stopper and containing 15 ml. of 3 per cent trypticase soy agar* allowed to harden on one side of the bottle. After the agar had solidified, 10 ml. of trypticase soy broth

containing 2.0 per cent sodium citrate was introduced with sterile precautions. Five ml. of venous blood or other infected material was then introduced aseptically with a needle and syringe. Ten per cent of the atmosphere was replaced with carbon dioxide.** The bottle was incubated in the vertical position at 37° C. The slant was inspected for growth and then the blood-broth mixture was allowed to flow across the slant twice weekly. Unless growth occurred earlier all cultures were incubated thirty days before being discarded.

Identification of the organism was based upon Gram stain, motility test, sugar fermentation, carbon dioxide requirement, urease production, growth on basic fuchsin and thionine dye plates, and agglutination by specific anti-Brucella serum.

Results

The symptoms experienced by these thirty-five patients are listed in Table I. Almost all patients had multiple and varied complaints. The predominant symptoms, such as weakness, sweats and general malaise, were nonspecific. Clear-cut symptoms relating to a specific anatomic system (digestive, respiratory, et cetera), usually were lacking. Symptoms of the disease persisted for an average of 4.6 months in the thirty-one patients where such data were complete. The range was from two weeks to fifteen months.

In spite of multiple symptoms there usually were few physical abnormalities (Table II). Fever was present at some time in all of the thirty-five patients but varied considerably in degree and pattern. In some only a transient, low-grade fever was recorded with a predominantly normal temperature even in the presence of bacteremia. Most patients had chills (Table I) and a diurnal fever to 103° F. or higher for a few days early in the disease but their temperature usually returned to normal in less than two weeks.* A plateau fever was never observed; although the temperature often rose to 104-105° F. in the afternoons, it usually declined in the evening and approached normal by morning. A genuine undulant fever was recorded in only nine of the thirty-five patients. The average duration of fever was 3.2 months (range = ten days to fifteen months) in thirty-two patients.

Lymphadenopathy was present in the majority. Usually the anterior and posterior cervical as well as the axillary lymph nodes were enlarged. The nodes were seldom more than moderately enlarged and never showed evidences of suppuration. Occasionally epitrochlear and inguinal lymph nodes were notably swollen. There was palpable enlargement of the liver in one-third and of the spleen in nearly one-half of the patients. However, neither organ was massively enlarged in any patient. Tenderness of the liver was elicited in only four patients, and the spleen was tender in only one-fourth of the patients in whom it was palpable.

External evidence of weight loss was seldom apparent although half the patients lost weight. Only five of thirty-five patients lost 20 pounds or more. The lumbar spine was tender and stiff in two patients having spondylitis and radiculitis. One of these patients also had a positive Babinski reflex and a hemi-hypalgesia to pin-prick. Unusual manifestations included a maculo-papular,

---

**We suspect that it is not necessary to add carbon dioxide for *venous* blood cultures. Venous blood (5 ml.) should contain adequate carbon dioxide. For three years duplicate venous blood cultures, with and without added carbon dioxide, were obtained. Of sixty cultures positive for *Br. abortus,* requiring added carbon dioxide on subculture, thirty-four grew in both Castaneda bottles on primary isolation, fourteen grew only in the presence of added carbon dioxide and twelve grew only in its absence. These results one might expect purely from chance.

*However, thirty-three of the thirty-five patients received some form of chemotherapy.

generalized rash and a tender, enlarged testicle each in a single patient. Thrombophlebitis and pulmonary infarction led to an empyema with a bronchopleural fistula in one patient. This man recovered but required extensive thoracic surgery and had a chronic empyema remaining five years after the onset.

The incidence of the most significant laboratory findings is given in Table III. A positive venous blood culture was obtained in all of the thirty-five patients. The organism was found to have all the typical characteristics of *Br. abortus* in thirty-four patients. In one patient the organism lacked the requirement for carbon dioxide upon primary isolation but had the other characteristic of *Br. abortus.** Culture of sternal bone marrow also yielded *Br. abortus* in ten of twelve patients at a time when they had demonstrable bacteremia. Serial blood cultures were obtained at intervals for as long as six years. Demonstrable bacteremia persisted after the onset of symptoms for an average of 2.8 months (range = two weeks to thirteen months) in thirty-three patients.

Agglutinins for *Br. abortus* were found in the serum of all the patients in a titer of 1:160 or over. The median initial agglutinin titer was 1:640 but the initial titer was only 1:160 in three patients and was 1:5120 in one patient Serial observations of the agglutinin titer were made in all patients. The maximum titer ranged from 1:160 to 1:5120 (Median = 1:1280). The persistence of agglutinins is of considerable interest. In thirty-four patients adequate serologic studies were available following the acute illness. These studies indicated that agglutinins persisted in a titer of 1:160 or greater for over three months in twenty-four patients, over six months in twelve, over twelve months in four and over eighteen months in two. Where agglutinins were followed to near or actual disappearance, a titer of 1:160 or over persisted for an average of 9.1 months in eleven patients (range = two weeks to 4.75 years). In three patients agglutinins persisted in a titer of 1:20 or over for fifteen, fifteen and twenty-four months, respectively, despite complete disappearance of all symptoms, physical signs and bacteremia many months before.

There was no evidence of anemia in any patient. The initial leukocyte count was seldom elevated. It was 10,000 or more per cubic millimeter in only two of thirty-five patients (maximum = 11,500, median = 6,000 and minimum = 2,500). The proportion of lymphocytes to neutrophiles was increased in every patient. The lymphocytes usually were small or medium in size and mature, although occasionally there were many immature leukocytoid lymphocytes in the peripheral blood. The erythrocyte sedimentation rate initially was normal in most patients, but it became markedly elevated in some. Stained sections of aspirated particles of sternal bone marrow showed granulomas resembling non-caseating tubercles in ten of twelve patients. Liver biopsies revealed similar granulomas in three of four patients. Serial liver biopsies also showed hemosiderosis and peri-portal fibrosis in one alcoholic bartender. There was no evidence of in-

---

*This strain grew in an atmosphere from which carbon dioxide was completely absorbed with solid KOH. It produced little H_2S and only moderate amounts of urease. Its growth was prevented by thionin but not by basic fuchsin. It was differentiated from strain 19 *Br. abortus* on methylene blue and thionin blue plates.[15]

TABLE IV. RESULTS OF CHEMOTHERAPY IN CASES STUDIED

Drug	No. of Patients	No. of Therapeutic Courses	Dose per Day	Duration of Therapy	Results (by Therapeutic Courses)		
					Recovered	Relapse

ACTH	7	7	100 mg.	3-10 days	2/7	3/7	4/7

volvement of the kidneys in any patient although one had definite orchitis.

Results of chemotherapy in thirty-three patients are summarized in Table IV. Two patients received no specific drugs or antibiotics. A rather large number of therapeutic agents was investigated. Although the total number of patients was not large, certain facts soon became evident. Sulfadiazine was bacteriostatic *in vitro* and only moderately suppressive *in vivo*. Streptomycin was strongly bacteriocidal *in vitro* but often failed to be beneficial in human brucellosis.[8] The combination of these drugs was more effective in experimental animal infections and in the human disease than either drug alone.[9,21,22] Toxic effects of streptomycin, such as drug fever, drug rashes and vertigo due to damage to the eighth cranial nerve, were serious disadvantages.

Aureomycin has been thoroughly tested and has proved to be the best therapeutic agent for human brucellosis in our hands.[2,20] It has been effective in suppressing symptoms, fever and bacteremia although some patients required more than one course before they recovered. No serious toxic reactions were observed although gastrointestinal irritation was troublesome in a few. Chloramphenicol and terramycin were used in a few patients. Chloramphenicol seemed slightly less effective than aureomycin but also produced fewer digestive disturbances. No hematologic toxicity was observed. Too few patients were given terramycin to permit valid comparisons. A combination of aureomycin plus streptomycin (or dihydrostreptomycin) was also studied in several patients after the method of Herrell and Barber.[10] The results were no better than those obtained with aureomycin alone. Fortunately no serious toxic effects were observed, probably because of our conservative daily dose of streptomycin.

Recently seven patients have been treated with corticotropin (ACTH) given alone or just prior to a course of antibiotics. The results have been reported in detail elsewhere.[1,19] Briefly, there was almost complete subsidence of symptoms and fever in spite of continued bacteremia as long as ACTH was given. Fever usually recurred as soon as the hormone was discontinued. No untoward effects were observed. Two recoveries were observed after ACTH alone; these may have been spontaneous.

Discussion

The diagnosis of human brucellosis is often difficult. The disease is most common in young men because of greater occupational exposure. It should be suspected in any febrile illness occurring in a packing plant employe, farmer or veterinarian. When a farmer is infected, it is worth while to examine all other members of the household since many unsuspected infections may be uncovered. *Br. abortus* may infect packing plant workers exposed to fresh pork as well as those coming into contact with beef only.[14] Although they form only a small fraction of the total number of sick patients, the individuals whose infection can be traced only to ingestion of unpasteurized milk or dairy products serve to emphasize the necessity for pasteurization of such foods.

As shown in Table I the symptoms are seldom diagnostic. Taken together with the occupational history, however, they may suggest the proper diagnosis to the experienced physician. The paucity of physical abnormalities (Table II) is striking; bedside examination of the patient alone never permits an unqualified diagnosis. The idea that an undulating, recurrent fever is the rule is not true; such a febrile course was present in only one-fourth of our patients. Some of the patients were afebrile for most of the duration of their disease. Only occasional patients had high fever and a severe illness. Complications such as orchitis, rashes and severe hepatitis were uncommon. The most frequent complication was spondylitis.

Skin tests with Brucella antigens have value in diagnosis in a febrile patient only if negative. A positive skin test does not indicate that an infection is necessarily active. The more widespread the disease, the less the value of skin tests. We do not believe they should be used except for epidemiologic studies because they often incite a confusing antibody response.

The most useful diagnostic tool has been the agglutination test. The tube dilution method has proved to be the most accurate available.[7] The initial agglutinin titer of all the patients in this series was 1:160 or over (Table III). However, the long persistence of agglutinins (average = 9.1 months) at this level, in the absence of symptoms or other evidence of activity, casts some doubt on the value of Brucella agglutinins in this titer as a measure of activity. The cause for agglutinins persisting for many months remains unknown but chronic intracellular parasitism in lymph nodes, spleen and liver seems the most likely explanation.

The only absolute proof of diagnosis is the isolation of Brucella from the patient. For this purpose we prefer venous blood cultures using the Castaneda double medium bottle.[4] Preferably three or more cultures should be obtained. Since the concentration of *Br. abortus* is low in the blood, if only a small amount of blood is submitted for culture, the organism may not grow. There does not seem to be any great advantage in using sternal bone marrow for cultures; in this series none was positive except in patients with demonstrable bacteremia. Bacteremia usually continues for less than three months with *Br. abortus* infections in human beings, although positive blood cultures were obtained in one patient thirteen months after the onset of his infection. Presumably the infrequent occurrence of chronic bacteremia is due to the infrequent occurrence of suppurative lesions. Histologic studies of biopsies of sternal bone marrow, lymph nodes and liver confirmed previous reports that the inflammatory changes consist of non-caseating granulomas made up to epitheliod cells and occasional Langhans giant cells.[11,23] In some patients liver biopsies showed considerable collections of mononuclear leukocytes in peri-portal areas adjacent to more or less well-defined granulomas. In one alcoholic patient serial liver biopsies showed considerable deposits of hemosiderin in bands of peri-portal connective tissue; there was no other evidence of hemochromatosis or cirrhosis of the liver.

Hematologic studies were helpful diagnostically. Leukocytosis was seldom seen even in the presence of complications. The prevailing pattern in the peripheral blood was a low or normal total leukocyte count with a relative increase in mature lymphocytes. Occasionally the appearance of numerous circulating leukocytoid lymphocytes together with fever, lymphadenopathy and splenomegaly caused some difficulty in differentiation from infectious mononucleosis.[18] However, heterophile antibody usually was present only in low titer and was readily absorbed with guinea pig kidney. The erythrocyte sedimentation rate was normal more often than is the case in most bacterial infections but it was not a reliable diagnostic aid.

The therapy of human brucellosis has undergone a gradual evolution in the past ten years. At first no treatment was offered. Early in the past decade sulfonamides were used but proved disappointing. Streptomycin, which seemed so strikingly effective in the test tube, also proved to be of little value in patients. The combination of these drugs improved therapeutic results but at the expense of serious toxicity caused by the streptomycin. Chloramphenicol has been abandoned because the results obtained did not seem to justify the risk of serious bone marrow depression.[24] In our hands aureomycin has proved the best of the antibiotics. However, there has been a disturbing number of relapses and these have not been prevented by the addition of streptomycin or dihydrostreptomycin. These antibiotics suppress the infection, fever and bacteremia but these effects are often only temporary and the ultimate recovery of the patient seems to depend upon his inherent powers of resistance. Antibiotics probably fail to be curative because they fail to penetrate infected intra- and extra-cellular foci.[16,17] Fever and toxicity can be controlled quickly with ACTH in spite of continued bacteremia. Thus ACTH may prove to be beneficial, when combined with antibiotics, for the treatment of the most severely toxic patients.

Since human brucellosis can nearly always be traced to an animal source, control of the human disease depends primarily on extermination of the animal reservoir. Pasteurization of milk and other dairy products is helpful but will not eliminate human brucellosis. Control of the disease in cattle, goats, sheep and hogs is a problem for veterinarians and public health officers, but the physician should be and is vitally interested. Whether vaccination, slaughter or quarantine of infected animals is the best policy may well depend upon local economic factors as well as the biology of the disease. Vaccination of human beings does not appear to be effective.

Summary and Conclusions

1. Thirty-five patients with brucellosis caused by *Br. abortus* were studied. Symptoms of the disease were multiple and varied. Physical findings usually were few and inconclusive.

2. *Br. abortus* was isolated from the blood of every patient. All had serum agglutinins ranging in titer from 1:160 to 1:5120. The diagnosis rested principally upon the epidemiologic and clinical history, the agglutination test and the blood culture. Only the last was decisive.

3. Aureomycin proved to be the most satisfactory therapeutic agent. There seemed to be no advantage in adding streptomycin or dihydrostreptomycin. Corticotropin (ACTH) controlled fever and toxicity but not bacteremia. Corticotropin may be a useful adjunct to chemotherapy in critically ill patients.

4. Control of human brucellosis rests upon pasteurization of dairy products and elimination of the animal reservoir.

ANTIBIOTIC THERAPY IN BACTERIAL ENDOCARDITIS

III. Penicillin O and Hypoallergenic Penicillins in Treatment of Subacute Bacterial Endocarditis

JOSEPH E. GERACI, M.D., and PHIL R. MANNING, M.D.
Rochester, Minnesota

THE TREATMENT of subacute bacterial endocarditis occasionally is complicated by reactions caused by sensitivity to penicillin. In 1943, Lyons reported that reactions to penicillin in the form of urticaria occurred in 5.7 per cent of 209 patients. Simon[15] stated that the incidence of all types of reactions to penicillin was approximately 7 per cent.

Evidence indicates that the incidence of sensitivity to penicillin is greater when large amounts of penicillin are used for long periods than when smaller amounts are used for shorter periods.[6] In the treatment of subacute bacterial endocarditis, which requires administration of large amounts of penicillin for a relatively prolonged period, the problem of sensitivity to penicillin is apt to be more common than in treatment of other conditions. The problem is particularly serious in this disease, because without proper treatment, subacute bacterial endocarditis is a fatal disease.

The commonest type of reaction of sensitivity to penicillin is urticaria, which usually occurs from seven to fourteen days after administration of penicillin. Urticaria may occur much more rapidly in patients who have previously received penicillin. The urticarial reaction is usually temporary and does not necessarily recur if penicillin is given subsequently.

Penicillin also may cause an erythemato-vesicular eruption. This lesion most commonly occurs on the hands, feet and groin.[10] Vesicular lesions may occur spontaneously in patients who have not received penicillin previously. It is considered that such patients have been sensitized by fungous infections of the skin.[4,8] The erythemato-vesicular lesions should be regarded with caution because of the danger of subsequent exfoliative dermatitis.

The treatment of reactions induced by sensitivity to penicillin is difficult to evaluate because of the frequently temporary nature of the condition, especially the urticarial lesions. It is often found that cutaneous lesions disappear even when use of penicillin is continued and that subsequent administration of penicillin to persons who have a history of sensitivity to penicillin may not cause any adverse reaction.

However, such reactions of sensitivity are persistent in some patients and may be refractory to one or more types of treatment. Nevertheless, when a potentially fatal disease such as subacute bacterial endocarditis is encountered, it may become almost obligatory to give penicillin. Various measures may be needed to combat these reactions of allergy. Unfortunately, no method is available to judge which method of treatment will be most successful in a given patient, so it is often necessary to be guided by the patient's history and to employ the several available methods of treatment by trial and error.

Simon[13,14] reported excellent results in decreasing the incidence of such reactions to penicillin by use of preparations containing a mixture of penicillin and an antihistaminic. Injection of these preparations is said to be well tolerated. Administration of solutions of penicillin containing 0.5 per cent of 2-[α (2-dimethylaminoethoxy) - α - methylbenzyl]-pyridine (decapryn) reduced reactions of sensitivity to penicillin from 6.5 to 2.4 per cent. When a 1 per cent solution of 2-[(2-dimethylaminoethyl) - 2 - thenylamino] - pyridine (histadyl) was added to penicillin, the rate of reactions was decreased to 0.5 per cent in a large series of cases, according to Simon. We have had no personal experience with these preparations.

Peck and his co-workers[9] have shown that hyposensitization attained by administration of small amounts of penicillin, with gradual increase of the dose, may be successful in the elimination of reactions to penicillin. This procedure is time-consuming and may not always be effective; however, we have used it with success in several cases of endocarditis.

Recently, interest has turned to various "hypoallergic" preparations of penicillin, such as penicillin O (allylmercapto-methylpenicillin). Reports

---

Dr. Manning is a Fellow in Medicine, Mayo Foundation, and Dr. Geraci is with the Division of Medicine, Mayo Clinic, Rochester, Minnesota.

concerning the effectiveness of these penicillins are conflicting. Siegal concluded that cross-sensitivity between penicillins O and G is the rule rather than the exception in patients who display persistent reactions. Volini and associates, however, used penicillin O in fifty-seven patients who had clinical symptoms of hypersensitivity to penicillin G; none of these patients showed untoward reactions to penicillin O. Adair and his co-workers stated that, "When therapy cannot be discontinued in the patient with a serious infection because of a hypersensitivity reaction, substitution of penicillin O for G can be considered a safe and beneficial procedure."

We are reporting the cases of three patients who had subacute bacterial endocarditis, who gave a history of sensitivity to penicillin G and who were treated satisfactorily with penicillin O. It will be noted that all three patients did manifest some reaction to penicillin O; however, it was considered that these reactions were much less severe than would have been expected with penicillin G on the basis of the patients' histories of previous reactions. Treatment in each of these patients was able to be continued to a successful conclusion.

Report of Cases

Case 1.—A forty-one-year-old white woman was admitted to the Mayo Clinic with a four months' history of daily fever as high as 102.4° F. (39.1° C.), night sweats, increasing fatigue, anemia and occasional chills. No previous history was present of rheumatic fever, rheumatic heart disease or a cardiac murmur. The onset of the disease had been gradual.

General examination revealed sinus tachycardia, minimal aortic insufficiency with a diastolic murmur at the aortic zone and a minimal apical systolic murmur. Cardiac size and rhythm were normal. Slight clubbing of the fingers was present and the splenic edge was just palpable.

Pertinent laboratory findings revealed mild anemia, an elevated erythrocytic sedimentation rate and microhematuria. Smear of the blood showed a few phagocytic reticuloendothelial cells and some toxic polymorphonuclear leukocytes. The leukocyte count was within normal limits. Two cultures of blood revealed the presence of Streptococcus mitis; this organism was inhibited by less than 0.05 unit of penicillin and by 1.5 micrograms of aureomycin per cubic centimeter of medium.

Because of a history of previous severe allergic sensitivity to penicillin G, the patient was given penicillin O and dihydrostreptomycin in combination. She received 300,000 units of penicillin O every three hours intramuscularly. Dihydrostreptomycin was given in doses of 0.5 gm. every six hours for a daily total of 2 gm. Tripelennamine hydrochloride (pyribenzamine) was given every six hours in doses of 50 mg. On the third day of treatment a mild pruritic maculopapular cutaneous eruption was noted on the neck and arms. This began to clear up by the end of the next day. At this time the injections of penicillin, which had been given only at one site, were given in various extremities and at different locations. The next day great intensification of the pruritus and the maculopapular erythematous eruption occurred, together with the appearance of a rash over the buttocks, the posterior aspect of the thighs and, to a lesser extent, on the calves, forearms, face and neck. Administration of pyribenzamine was increased to every four hours and calamine lotion was used for the pruritus.

Administration of the antibiotics was continued despite the extensive cutaneous disturbance and finally the eruption began to subside. At the end of the fourteenth day of treatment the rash had cleared almost completely except for the tips of the third and fourth left fingers and one of the fingers of the right hand. These regions revealed whitish zones of dead skin. These zones became more numerous and coalesced, so that exfoliation of the skin of the hands eventually occurred. The patient responded well to this short term of combined therapy with penicillin and streptomycin. Follow-up studies twelve months later revealed that she continued to be well. No cutaneous tests for sensitivity to penicillins O or G were performed and no penicillin G was given either during or after treatment with penicillin O.

Case 2.—A seventy-four-year-old white man was admitted to the clinic with a five months' history of anorexia, easy fatigability, loss of strength and weight, mild arthralgias and low-grade fever, which on occasion was as much as 103° F. (39.5° C.). Six months before the onset of these symptoms the patient had undergone transurethral prostatic resection. A diagnosis of subacute bacterial endocarditis had been made at home. The organisms that had been isolated were thought to be nonhemolytic streptococci, which were found to be resistant to all the more commonly used antibiotics except chloramphenicol (chloromycetin). He had been treated with 3 gm. of chloromycetin per day for four weeks without success. Use of penicillin had been followed by extensive reactions resembling exfoliative dermatitis over several parts of the body. The patient had been advised never to have penicillin again.

General examination showed questionable petechiae on the buccal mucosa. The blood pressure was within normal limits, as was the cardiac rate; cardiac rhythm was normal. The heart was not enlarged. A loud systolic murmur was heard at the aortic and mitral zones and was loudest at the apex. The prostate was enlarged. No clubbing of the fingers or splenomegaly was noted. The patient did not look ill.

Results of laboratory examination disclosed mild anemia, elevated erythrocytic sedimentation rate and microhematuria. The total leukocyte count and a differential count were normal. No phagocytic reticuloendothelial cells were noted in smears of blood. Values for blood urea were within normal limits; a roentgenogram of the thorax revealed nothing abnormal. Three cultures of the blood disclosed micrococci, the species of which was undetermined. Studies of sensitivity revealed that this organism was inhibited by 1.6 units of penicillin per cubic centimeter of medium. It was not inhibited by more than 50 micrograms of aureomycin, terramycin or chloromycetin, or by more than 100 micrograms of dihydrostreptomycin per cubic centimeter.

Because of the great resistance of the organism to most antibiotics and its relative sensitivity to penicillin, and because of the history of prior hypersensitivity to penicillin G, it was decided to treat the patient with penicillin O. A total of 900,000 units of penicillin O in divided doses was given on the first day. This amount was increased to 2,000,000 units the next day; daily treatment with this amount was continued. On the third day of treatment, mild erythema and edema associated with slight pruritus appeared in the inguinal regions and the upper parts of the thighs. These conditions subsided in two days even though treatment was continued, but some scaling of the superficial layers of the skin occurred during the next few days in these regions. After seven days the daily dose was increased to 4,000,000 units and was continued at this level for sixteen days. On the fifteenth day of treatment, intramuscular administration of procaine penicillin G was begun in small doses; the daily dose was gradually increased until 5,000,000 units of this form of penicillin was given per day. Then penicillin G was given by continuous intravenous drip, at first in small doses and then in increasingly larger amounts until a total dose of 10,000,000 units per day was being given in this manner. This amount was administered daily during the last nine days of treatment. Dihydrostreptomycin in amounts of 2 gm. per day for the first two weeks in divided doses and 1 gm. per day for the remainder of the period of treatment was also used. In addition, the patient received 50 mg. of pyribenzamine every six hours during the first two weeks of treatment. Administration of probenecid (benemid) in doses of 0.5 gm. four times a day was instituted in an attempt to enhance the concentration of penicillin in the blood.

The duration of treatment was thirty-six days, during which a total of 183,500,000 units of penicillin and 49 gm. of dihydrostreptomycin was used. The patient responded well to this program except for a mild psychosis induced by fatigue and exhaustion for several days; this disappeared before treatment was terminated. Follow-up studies in this case after an interval of some months indicated that the patient was well and working.

Case 3.—A fifty-eight-year-old Negro was admitted to the clinic with a six months' history of malaise, easy fatigability, recurrent arthralgia involving the shoulders, sweats, chills, fever and loss of weight. During the three months prior to admission he had experienced a chill almost daily, together with a fever as high as 104° F. (40° C.) and diffuse sweating.

General examination disclosed evidence of recent loss of weight. The heart did not appear enlarged. A minimal systolic murmur was present at the cardiac apex; sinus tachycardia was noted and the blood pressure was 120 mm. of mercury systolic and 75 disastolic. No clubbing of digits or splenomegaly was present.

Results of laboratory examination disclosed severe anemia, the value for hemoglobin being 6.8 gm. per 100 cc. of blood; the leukocyte count was normal and a differential count disclosed 87 per cent polymorphonuclear leukocytes. The erythrocytic sedimentation rate was 98 mm. at the end of the first hour (Westergren method). The value for blood urea was increased. Urinalysis showed albuminuria, michropyuria and hematuria. Two cultures of the blood disclosed the presence of Streptococcus mitis. Results of tests for sensitivity revealed that the organism was inhibited by 0.1 unit of penicillin, by 1.5 micrograms of terramycin and by 3.1 micrograms of aureomycin per cubic centimeter of medium.

Because of a history of previous reactions to penicillin G and because of the unavailability of penicillin O at the time, administration was begun of 3 gm. of terramycin and 1 gm. of dihydrostreptomycin per day in divided doses. Additional studies *in vitro* after treatment was started disclosed that terramycin alone had only slight bactericidal action and that the organism was not inhibited by more than 100 micrograms of streptomycin. A combination of terramycin and dihydrostreptomycin did not show enhanced bactericidal activity. Penicillin and terramycin together did not show increased effectiveness; indeed, this combination showed less bactericidal effect than did penicillin alone. Penicillin and streptomycin on the other hand did exhibit greater killing power than did penicillin alone. Despite this additional information it appeared advisable to continue use of the combination of terramycin and dihydrostreptomycin and to avoid use of penicillin G.

Treatment was continued for fourteen days and then stopped. The patient's temperature, which had been 103° F. (39.5° C.) before treatment was started, decreased to normal two days after onset of treatment. Cultures of blood failed to reveal any organisms and the patient was considerably improved symptomatically. Two weeks after treatment was discontinued the temperature increased and chills reappeared; cultures of blood made at this time again disclosed streptococci. Studies of sensitivity at this time revealed that the organism was inhibited by more than 6.2 micrograms of terramycin, 0.8 unit of penicillin, 6.2 micrograms of aureomycin and 25 micrograms of streptomycin per cubic centimeter of medium. The patient was then given from 600,000 to 3,000,000 units of penicillin O per day; it was given intramuscularly every three hours in divided doses. After the first dose of penicillin O, urticaria developed in the left lower eyelid and at the base of the left side of the neck. Diphenhydramine hydrochloride (benadryl), in a dose of 100 mg., was given; use of penicillin O was continued. After the fourth injection of penicillin O, the onset of mild redness, swelling and tenderness was noted in the terminal portions of all the fingers of both hands. These reactions had occurred after previous use of penicillin G and had been so alarming that the family physician had warned against further administration of penicillin. By the next morning the cutaneous lesions had disappeared and use of penicillin O was continued in larger daily doses without further reactions.

Dihydrostreptomycin was given as before. This schedule of treatment was continued for eleven days. Then procaine penicillin G in daily amounts of 3,600,000 to 4,800,000 units was administered along with dihydrostreptomycin. Finally, penicillin G was given by continuous intravenous drip, the daily dose averaging about 10,000,000 units; use of dihydrostreptomycin was continued. The patient received a total of 650,000,000 units of penicillin, 83 gm. of dihydrostreptomycin and 27 gm. of terramycin. Numerous cultures of blood obtained during the period of treatment failed to reveal organisms. Subsequent follow-up information revealed that the patient was well one year later.

Comment

Because reactions of sensitivity to penicillin are frequently temporary and fluctuate greatly, it is not possible to state dogmatically that these patients could not have been treated initially with penicillin G. However, because of the history of previous severe reactions to penicillin G, it was considered unwise to give this preparation at the onset of treatment. The considerably milder nature of the reactions with penicillin O indicates that the latter form of penicillin was of benefit in the treatment of these patients.

One can only speculate concerning the type and severity of the cutaneous reactions that might have developed in these three patients had they been given penicillin G initially. In the first case, the extensive erythematous maculopapular rash had begun to clear by the end of the fourteenth day of combined therapy with penicillin O and dihydrostreptomycin, but exfoliation of the skin of the fingers and hands was beginning to develop. Appearance of this reaction sooner or a longer period of treatment would have necessitated cessation of treatment with penicillin in this patient. It was considered that successful short-term treatment with penicillin O in combination with dihydrostreptomycin[3] enabled us to eradicate the infection; this might not have been achieved if it had been necessary to use either penicillin G or penicillin O alone or in combination with streptomycin for the conventional period of treatment of four to six weeks. In the second case, the exfoliative reaction that occurred with penicillin O was considerably milder than that after previous use of penicillin G and it cleared up in several days while treatment with penicillin O was continued. In this case also, it was considered that successful therapy was possible because of the use of penicillin O, particularly in view of the fact that the organism was extremely resistant to all the other more commonly used antibiotics. In the third case, the reaction to penicillin O was considerably less severe and more transient than that seen after use of penicillin G. After failure of combined treatment with terramycin and dihydrostreptomycin, it was still considered hazardous to start with penicillin G; therefore penicillin O was substituted with good results.

It is evident that cross-sensitivity was present between penicillins O and G in all three cases; however, penicillin O apparently caused relatively mild and transient reactions. While it is evident that penicillin O is not the final answer to the problem of sensitivity to penicillin, it offers one more approach to the treatment of patients who have subacute bacterial endocarditis, who are sensitive to penicillin G and in whom use of penicillin is indicated.

In the treatment of a potentially fatal disease, such as subacute bacterial endocarditis, it is valuable to have available several methods of treatment to combat sensitivity to penicillin. Given a patient in whom a diagnosis of endocarditis is established and who presents a history of sensitivity to penicillin, the physician may approach the problem of therapy with the following thoughts:

1. If the history is that of a mild urticarial or erythemato-vesicular eruption, one may begin with conventional treatment and give antihistaminics when the reaction of sensitivity manifests itself. As was done in the three cases we have reported, administration of antihistaminics may be started at the onset of therapy.

2. If a history of moderately severe cutaneous reactions is present, one may begin treatment with a combination of antihistaminic and penicillin in solution given by the continuous intravenous route, as suggested by Simon.

3. Penicillin O may be used, with or without addition of an antihistaminic.

4. If these forms of treatment are of no avail, then one can test the sensitivity of the isolated organisms to the other commonly used antibiotics and to combinations of antibiotics, in a search for synergistic bactericidal effects. In the rare case in which penicillin cannot be used, it may be possible to eradicate the infection by use of another antibiotic or combination of antibiotics that has been demonstrated to be of value by studies *in vitro*. Occasionally it is possible to use successfully one of the bacteriostatic agents, such as terramycin or aureomycin, either alone or in combination with dihydrostreptomycin or other anti-

biotics.[5,11] However, experience has indicated that use of such bacteriostatic agents, either alone or in combination, is of limited value in the treatment of bacterial endocarditis.[2]

5. If all these methods have failed, one must resort to the costly and time-consuming method of hyposensitization to penicillin. This phase of the problem has been thoroughly reviewed by Siegal.

Summary

Three patients who had subacute bacterial endocarditis and who presented histories of previous severe reactions of sensitivity to penicillin G were successfully treated with penicillin O. All three patients manifested mild reactions of sensitivity to penicillin O; these reactions were insufficient in degree to warrant cessation of administration of this form of penicillin.

Penicillin G was administered subsequently in gradually increasing doses in two of these three cases without any untoward reactions. Antihistaminic drugs were used in all three cases in an attempt to minimize the extent of reactions.

CAR DEATHS COST LIFE INSURERS $69 MILLION

Automobile fatalities brought 39,000 life insurance death claims in 1952, representing aggregate payments of $69,000,000 in the year, the Institute of Life Insurance reports.

The life payments stemming from motor vehicle deaths in 1952 were very nearly as great as all life insurance death benefit payments annually for all causes of death in the late '90s, the Institute said.

"While the dollar cost is purely incidental to the personal tragedies involved, it does stand as a warning of a huge public loss, even when insurance payments are made," the Institute commented.

Life insurance purchases in the United States in 1952 set an all-time record, it was reported by the Life Insurance Agency Management Association.

Life insurance purchases in the United States in January were 16 per cent greater than the volume in the corresponding month of last year, and were at a record level for January.

A LOOK BACKWARD

OWEN H. WANGENSTEEN, M.D.

Professor of Surgery, University of Minnesota Medical School
Minneapolis, Minnesota

MY FRIENDS in the Academy:

There are ordinarily two happy moments surrounding election to High Office. First, as one contemplates with pride the esteem of his colleagues which placed him there, and then when he is relieved of the responsibilities of the office. You have shown me previously many evidences of your affection, a sentiment which I reciprocate and for which I am very grateful. You have placed me greatly in your debt. And now that I am about to join that group of distinguished past presidents of this Academy, I want to acknowledge with a sense of pride this additional mark of your confidence. Life often rewards us many times beyond our true merit. As I stand before you now with "emotional knees," I have only one claim upon you—and that is one of profound gratitude for your kindly acceptance of me.

Much of what happens to us in life is accident: Who our parents are; where we grow up; who our associates are; who our teachers are; under what influences or spells we come, and a host of other considerations which determine in an important manner the fate of any one of us.

My appearance before you tonight is in the real sense an accident. I never wanted to be a doctor. The reasons, whatever they were, seemed very real to me then. My father was a small town business man in a village in Western Minnesota in the Red River Valley, and we lived on a farm on the edge of the village. My only ambition was to be a farmer. Living close to nature, surrounded by a host of living and growing plants and creatures filled me with a sense of the joy of living, of being useful and of being a part of an important scene. It is still a pleasant dream! However, my father had other plans for me. He was intrigued by my anxiety over sick animals, horses, cows, and pigs alike. My only concern was for them.

A number of years ago—in 1926, I believe it was—Ray LaVake asked a number of us to tell at a Nu Sigma Nu banquet what the resolution of forces was which led us to become doctors. To a few of you, therefore, my story is repetitious. But I repeat it here only to ~~emphasize the point~~ that what we are and do is often in large measure mere accident. One spring, while I was still a student in High School, we had on the farm about fifty sows that could not farrow their young. The first two sows with their unborn litters we lost while waiting, on the advice of our veterinarian, "for nature to take its course." I scurried through the *Breeders' Gazette, The Farmer,* and several books on the veterinary problems of the farmer which occupied a row on our modest book shelves. A snaring apparatus procured through the advertising columns of one of these journals proved useless. Much to my amazement, I found my own hand the best instrument to deliver these pigs. The effort cost me about three weeks of school, for as those of you who have had obstetrical experience know, these obstetrical assignments are time consuming, especially for multiple births. For me it was a task that had to be done. I can still feel, after these many years, the warmth of my father's sense of pride in the accomplishment. Three years in college went by before I capitulated to my father's plea to have a go at medicine. That last summer on the farm, during World War I, when help was very scarce, it fell to my lot to haul manure every day during a hot spell of weather for a period of about three weeks between haying and harvesting. Well, it was too much. Anything, I thought, would be better than this! So through the portals of pigs and manure, I come before you tonight.

And what a thrilling experience it has been to be a doctor! You, who have thoroughly enjoyed the experience such as I have, know whereof I speak. I retell this story for another reason—to emphasize the great influence which the ferments of time and experience work silently upon our minds and outlook. That which we reject in adolescence, we come with more experience not only to accept, but to embrace. Our language stands in need of a good word to connote this transition from rejection to acceptance. How the interaction of a number of forces can be influenced favorably to bring such conversions about is probably one

---

Presidential Address, presented at the Minnesota Academy of Medicine, January 14, 1953.

of the most important problems of education. From my own experience, I would say that the most helpful catalyst other than time, in this complicated chemical reaction, is work. Happy and fortunate is that man upon whose shoulders the yoke of work fits comfortably! Work matures the adolescent mind. It soothes the troubled mind, and is the best balm for the abrasions and trials of life. If work is the curse of heaven, how sweet can its blessings be?

1887

Almost sixty-six years have elapsed since the founding of this Academy. In that very year (1887), Edward Bellamy wrote his famous Utopian novel, "Looking Backward," in which he depicted life in America in the year 2000. It has been said that, of books published in the last twenty-five years of the nineteenth and the first twenty-five years of the twentieth century, Bellamy's "Looking Backward" has had more influence on the progress of thought that any other book, save "Das Kapital," by Karl Marx. Forward looking and imaginative as Bellamy's book was, accomplishment has exceeded Bellamy's most startling of many clairvoyant prophecies on all scores, save that of human behavior. The "Rosebush of Humanity" which was to grip the peoples of the world in a warm glow of fraternity and love of his fellow man, such that war would cease to exist and thereby make standing armies and navies unnecessary—that rosebush still remains a figment of the imagination, expressed now and then in the buoyant and expectant hopes of many peoples who would like to believe that the differences which separate people can be resolved by means other than war. The echoes of the battles of words coming from the conclaves of the representatives of governments where we believe these issues should be resolved peacefully tell us plainly that there, too, as in most spheres of human activity, a relentless struggle for advantage and the upper hand is continuously in progress. Recourse to dialectics never was and never will be the pass-key to salvation in any endeavor. We must look to devices more promising than words before the "Rosebush of Humanity" can awaken the sympathies and still the combativeness of man such that man will come to believe that his own welfare and that of all peoples is dependent upon a spirit of co-operation, mutual helpfulness and trust.

The First Meeting of the Academy

The first meeting of the Minnesota Academy of Medicine was held at the Ryan Hotel in St. Paul on November 5, 1887. The transactions of the meeting were published in the November 15 issue of the *Northwestern Lancet,* the forerunner of the present *Journal-Lancet.*

We are told in an editorial comment on that meeting by the editors, Alex J. Stone and William Davis (Associate Editor), that approximately thirty-five of the forty men made members in two previous organizational meetings were present. They also commented as follows:

> "It is a humiliating confession of the superiority of body over the mind, that no medical society having frequent meetings can hope to keep alive the interest of its members, unless it furnishes something in the way of a supper at its gatherings. The Academy recognizes this fact, but it seems to us it is rather inclined to overdo the matter, if the spread furnished at the Ryan is a sample of what is to be expected at the meetings."

The editors then went on to suggest that they regarded it as preferable to reverse this order of things and to have the scientific papers read before the repast.

During the twenty years that I have been privileged to be in attendance at these meetings, I must say the Academy and the Town and Country Club have collaborated to provide a friendly atmosphere and to serve dinners of a rare quality which have left a wonderful relish on our mental palates that has survived long beyond the mere enjoyment of such nice occasions.

John F. Fulton, the first president of the Academy, delivered his inaugural address on the occasion of the first meeting—a procedure which has been reversed such that the president now finds it his duty to try to say a few words appropriate to the occasion when he leaves the stage rather than when he first comes on. This arrangement can be a source of real comfort to the speaker, for no one expects any evidences of serious thought in a swan song. In Kansas, the State bird is the mythical Jayhawk, which is said to fly backward, because it is more interested in where it has been than where it is going. Now, I presume, the only survivor of this professed greater concern for the past than for the future is typified in the addresses of retiring presidents of professional and scientific organizations. Inasmuch as the incoming president of this Academy is known to all the members a year in advance, a return to the original plan of having the president look ahead rather than back might bring the presiding officers to a fuller realization of their important responsibility. In any case, let me say that I wish I could feel that someone happening upon the pages of this presentation sixty-six years hence could reread these lines with a fraction of the pleasure with which I perused the forward-looking and stimulating paper of Dr. Fulton. It was a worthy inaugural for an organization which survived the pains of birth and has now come of age.

The other paper of that first meeting of the Academy was read by George F. French and dealt with the sexual problems of uncongenial marriages from the standpoint of the female. Ten persons participated in the discussion, all distinguished names of their day and well-known to most of us. Interestingly enough, a good share of the discussion hedged about the ills and prevalence of masturbation in the female, a subject that most physicians now are content to ignore, or when it needs attention to direct to the psychiatrist, the only person believed to be urbane and erudite enough to handle a subject of such delicacy with any suggestion of competence.

Thereafter for long years the Academy met alternately at monthly intervals, save for the summer season, at the West Hotel in Minneapolis and the Ryan Hotel in Saint Paul. In May, 1900, the meeting place was changed to the Minnesota and the Minneapolis Clubs. Subsequently, meetings were held at the Commercial Club in Saint Paul and the Minneapolis meetings returned to the West Hotel. In February, 1907, meetings were renewed at the Minnesota and the Minneapolis Club. Since the April meeting of 1911, with few exceptions, the Academy has continued to meet at the Town and Country Club.

On the occasion of Osler's visit to the Twin Cities in October, 1902, Osler also addressed the Academy. The subject of his address was "License to Practice" and the meeting was held at the State Capitol in the Hall of Representatives because of the larger meeting place and the interest of legislators in Medical Practice Acts. It probably should be said here that when Osler spoke on the Campus, President Northrop had to discourage student attendance at the lecture. How times have changed since then! Lectures on the Campus now, even by men of national prominence in medicine, are attended often by only a thin smattering of medical students. It is even problematic whether the announcement of a lecture by Kinsey on the vagaries of sex behavior would draw the students out to an extracurricular exercise. These reactions on the part of students are difficult to understand. What is required, they will do, but there appears to have been since World War II a growing apathy on the part of students toward unassigned tasks. It is not a healthy sign.

In 1887, when the meetings of the Academy began, it was ten miles between the populated borders of the Cities. Transportation was by train or by horse and buggy. Whereas a horse-drawn Street Railway system had been operated in both cities since 1875, it was December, 1889, before the first line was electrified, a process which was not completed for all the lines until 1892. The first inter-city line became operative in 1890.

How times have moved on since then in means of communication and travel! That our traffic problem still needs study and improvement, I believe all of us will concede freely.

Awakening of Interest in Medical Education

The first meeting of the Academy took place about two years before the beginnings of the Medical School of the University of Minnesota. The year our Medical School opened its doors (1889), a more significant event for greater Medicine occurred in Baltimore with the founding of the Johns Hopkins Hospital. With the aid of John Shaw Billings, Librarian and founder and builder of the Surgeon-General's Catalogue to medical literature, Daniel Coit Gilman, President of Johns Hopkins University, began the task of building a strong Medical School Staff. That departure from current practice in looking beyond the local scene for talent with which to fill the important posts in Medical Schools, has come to have great importance for Medicine in this country. C. W. Eliot, President of Harvard University, had begun as early as 1870 the renovation of the existing proprietary scheme of instruction, by which the Faculty pocketed the tuition fees. Two interesting letters of this period from Oliver Wendell Holmes to his friend, Motley, depict the opposition of the Faculty to these suggested innovations. Holmes' sympathies too were on the side of the Faculty. He characterized Eliot's efforts at reorganizing the Medical

School as flopping it over like a flapjack in topsy-turvy turmoil. Eliot won out and reorganized the Faculty on a true University basis, incorporating the Medical School as an integral part of Harvard University. Though carrying the name, the Harvard Medical School was, in reality, and had been since 1810, a voluntary proprietary organization, running its own affairs. Harvard University having no hospital of its own was, of course, unable to effect such sweeping changes as Gilman had set in motion at Hopkins. Presently, however, the movement of house-cleaning in the medical schools was in full-swing, and shortly after the publication of Abraham Flexner's report (1911), unmasking the existing deplorable condition of most medical schools in the country, the proprietary schools began to disappear. A reorganization of our own Medical School began with the coming of President George Edgar Vincent in 1911, and between 1914 and 1917 the plan of having all full-time teachers in the preclinical sciences had been completed. At the very same time at Johns Hopkins, the plan of having all the Heads of the Clinical Departments on full-time had been initiated—a plan that set the pattern for all medical schools in the country, and one which has now become standard practice in most of them.

An Exciting Period

There probably has been no more exciting period in the history of medicine than the years which saw the founding of this Academy. The battle of words over the contagiousness of puerperal fever had been fought and won, though even this victory failed to connote to the profession the great importance of the work of Pasteur (1862) and Lister (1867). When Lister came to this country to the first Centennial celebration in 1876, his reiteration of the importance of the antiseptic principle in surgery fell upon unprepared minds. In any case, when President Garfield was shot in 1881, the frequency with which his wounds were probed by many well-known surgical consultants, without any allusion to employment of Lister's antiseptic methods, suggests that Lister's teachings had fallen on deaf ears. Certainly all of the Consultants must have read some of Lister's papers and some of them must have heard his oration in Philadelphia at the time of the Centennial. All of which goes to indicate that the transference of knowledge from one area of learning to another is rarely, if ever, an overnight phenomenon. The ready acceptance of anesthesia by the entire medical world is, of course, a notable exception. And the more recent success of the sulfonamides with phlegmonous inflammations had prepared the way for ready acceptance of penicillin. Moreover, use of the experimental method in these latter researches lent simultaneous incontrovertible proof of the protection afforded by these antibiotics.

By 1887, when this Academy came into existence, the science of Bacteriology was well on its way. The cause of a host of bacterial diseases had been resolved. Meaning and understanding suddenly seemed to have penetrated into the aura of confusion which enveloped most diseases. Every physician lived in an atmosphere of hopeful expectancy. The discovery of the cause of many baffling affections was being made several times a year. With the employment of new techniques, the mysteries of the unknown in medicine were being probed with more success than had attended the efforts of countless observers over more than twenty centuries. The veil of despair was being lifted. There were evidences on the horizon of restoration of public confidence in medicine. For the first time in history, medicine became the recipient of magnanimous benefactions and bountiful philanthropy. Little wonder that Fulton, in his inaugural dissertation, was prompted to assert that abdominal surgery has been placed upon a basis of scientific accuracy.

Leeching and Blood-letting Still in Evidence

Still, all the useless therapeutic devices of the past had not yet been given up. John Ashhurst, editor of the International Encyclopedia of Medicine and Surgery, writing of the treatment of intestinal obstruction, said in 1886:

> "I have no hesitation in saying that the remedy of prime importance is direct depletion by blood letting. I would have no hesitancy in using it if leeches could not be procured. I have seen the whole aspect of a case changed by the application of leeches immediately over the inflamed aspect of the bowel. If the patient is a vigorous adult, at least 12 ounces of blood should be taken away. . . . After leeching, the whole abdomen is covered with mercurial ointment and a warm mush or hop poultice, then applied over all."

The poor hereditary background of the surgeon, as represented in part by the modern barber pole, together with observations of his sanguinary practices at operation, would appear to justify the disparaging reference of leech, which even nowadays is occasionally applied to surgeons. But let it be remembered that in the John Wycliffe Bible of 1382, St. Luke admonished, "Leech, heal thyself." Now, you and I know from an acquaintance with the King James version of 1611 that this allusion was to physicians!

A century before the birth of this Academy, the attitude of John Coakley Lettsom, one of the founders of the Medical Society of London, toward blood letting was stated in this well-known doggerel—

> "When people's ill, they come to I,
> I physics, bleeds and sweats 'em;
> Sometimes they live, sometimes they die,
> What's that to I? I lets 'em."

There is little evidence that the practice or its justification in such terms, increased the confidence of the public in the Medical Profession.

And if one scans the medical texts of John Ashhurst's day, it will be found that leeching and bleeding were still being advised for a number of disorders. In 1892, the very year in which Osler presented on the Campus of the University of Minnesota his memorable address on "Teacher and Student," the first edition of his great textbook, *Principles and Practice of Medicine* appeared. In it, Osler said concerning blood letting: "The reproach of Van Helmont that 'a bloody Moloch presides in the chairs of medicine' cannot be brought against the present generation of physicians. During the first five decades of this century, the profession bled too much, but during the last decades, we have certainly bled too little. Pneumonia is one of the diseases in which a timely venesection may save life." This indication for phlebotomy was still to be found in the eighth edition of the same text, which the medical student of my day read. Napoleon once remarked that there are evidences of Charlatanism in every age. The next generation will probably find palpable evidences of its survival well into our present period. And on that score the advice of a brother physician of nineteen centuries ago is worth heeding. Said Luke: "Thou hypocrite, cast out first the beam out of thine own eye, and then shalt thou see clearly to pull out the mote that is in thy brother's eye." Mote and beam in the Revised Standard Version of the Bible have become speck and log. Though with a ring of less eloquence, let us hope that this restatement of the metaphor may come to have increased meaning for its readers.

More than twenty years were to intervene beyond the founding of this Academy, before the transfusion of blood came to supplant phlebotomy. It is only in our own day that we have come to appreciate fully how complicated a scientific procedure the transfusion of blood can be. And refinements and improvements are being added continually. Such is the history of all progress!

Vital Statistics

The story of the birth of Christ tells us that the Romans had their registries for the recording of the census. There is no evidence of a regular system of registration of births, marriages and deaths prior to the institution of the practice in Geneva in the middle of the sixteenth century. Lord John Russell introduced a plan for the registration of vital statistics which the British Parliament enacted as law in 1836. Massachusetts began its scheme of registration of vital statistics in 1842. In the recording of the seventh federal census in this country in 1850, the first attempt was made to obtain figures on mortality for all the States in the Union. Minnesota, together with New Mexico, Oregon and Utah, were then still listed as Territories. Minnesota became a State in 1851. This interesting report was prepared under the direction of J. O. B. DeBow, Superintendent of the Census, and was published in 1855.

The "Zymotic" diseases were responsible for 40.8 per cent of the deaths in the 1850 census. Diseases of the respiratory system stood second in importance, being responsible for 16.9 per cent of the total mortality. Consumption, as such, was not mentioned by name. However, tuberculosis and pneumonia undoubtedly were the large contributors. Cholera, dysentery, fever, typhoid fever, scarlet fever and croup in that order were the most frequent causes of death listed under zymotic diseases. And in the new Blakiston edition of Gould's Medical Dictionary of 1949, the word zymotic is not to be found! And the threat of these diseases disappeared long before the word.

Geography and Disease

The year before this Academy came into being (1886), a Report on the Mortality and Vital Statistics of the United States came into print from the Government Printing Office at Washington under the authorship of John S. Billings, Surgeon of the United States Army. It was a compilation derived from the tenth census of 1880. The text contains many maps in color depicting the importance of geography upon mortality and the incidence-location of fatal diseases. As we examine these interesting maps now, it is quite apparent to anyone that many factors had to do with the reported incidence of these diseases. But probably more important than any other consideration for us is to recall now that, in the main, geography had little, if anything, to do with these diseases. All of them like tuberculosis, diphtheria, scarlet fever, typhoid fever, and a host of others were found to have specific causes. In only a few diseases, typified by malaria, have geographic studies been of primary importance in tracing down the actual causative agents. At best, such differences in geographic distribution are only suggestive. Ultimate causes must be sought in the more critical areas of thinking and research. Those who are presently enamored of the importance of geography in the study of cancer might well study these maps compiled by the Bureau of the Census in 1886.

Suggestions of Strife Between Specialists and General Practitioners Are Not of Recent Origin

"The chief objection brought against specialties is that they operate unfairly against the general practitioner in implying that he is incompetent to properly treat certain classes of disease and narrowing his field of practice." Lest some of you conclude that this was a recent expression from a member of the Academy on General Practice, let me hasten to add that this statement was contained in a Report of the Committee on Specialties of the American Medical Association published in the transactions of their Journal for 1869. It is obvious therefore that long before the beginnings of this Academy there was a feeling of competition between those who professed to be Specialists and those who accepted the role of General Practitioners.

We see about ourselves everyday evidences of a regimented society. Every Utopia reveals unmistakable traces of such regimentation. There is no Heaven without a Hell; no State in any era of civilization or in any projected Utopia without its prisons, hospitals and almshouses. Such has always been the condition of society. Regimented as we are today, I know of no imaginary Utopia in which the individual enjoyed as much freedom as we have today. We who are privileged to live here in America need to recount our blessings frequently.

Medicine could not deliver a good brand of medical practice to the public today without a large number of General Practitioners. Will that be the situation in the year 2000? Who can tell? I have the impression that if there were available now an adequate number of places for satisfactory training in all the specialties of medicine and surgery, which training would be fully acceptable to Boards which are authorized to pass judgment upon the adequacy of such training—if such places of training were to become generally available, I could well believe that the clinic idea to which the Brothers Mayo lent such great impetus might well become the standard condition of practice throughout our country. I am inclined to believe that if such training areas were available that the idea of broader specialty training might find acceptance with both the public and physicians. However, only time will tell. It certainly is not a development that can come about readily.

The Medical Profession needs to work out for the welfare of the public, as well as for its own good, happier existing relationships between General Practitioners and Specialists. Obviously, there may have to be some give and take on both sides. What is best for the public will eventually prevail, and in the long run is best for medicine too. The General Practitioner is usually the first contact of a patient with the Medical Profession, and properly so. He is medicine's first-line consultant. He must be prepared to assume some responsibility for every type of illness.

The patient and the public sometimes view with alarm early contact in an illness with a Specialist. The public is inclined to believe, on the basis of earlier experience, that the Specialist is too narrow and myopic in his views; that he is too inclined to assess the patient with high-powered lenses in his own field of interest, screening all other areas out of focus. Specialists probably do better on this score than in earlier years, but in general the criticism is still valid. Very few Specialists deserve the term of Physician in a limited domain. Cultivation of a universal focus of interest on all functioning parts of the patient's anatomy is not easily achieved by any physician, no matter what his profession of interest is.

The Academy

Academy is a spirited word. Ever since Plato taught in the olive groves of Acadame, Academy has come to be synonymous with the cultivation of learning. Distinguished societies have adopted the name. In Europe, particularly in France, Academies of Literature, Arts and Sciences, as well as in the special provinces of Learning, came early to typify an interest in scholarship at the highest level. Milton in his well-known tract on education, conceived of an Academy as something intermediate between a University and a College. In our country, an Academy has come to be synonymous with a school of instruction. The only survivals in our telephone book listed under the title are an Academy of Accountancy and another where the art of horseback-riding is taught.

The New York Academy of Medicine

The New York Academy of Medicine celebrated its first Centennial in 1946. Many of you are undoubtedly familiar with the excellent volume by Philip Van Ingen, published by the Columbia University Press in 1949, setting forth the History of that Academy. From small beginnings, the New York Academy of Medicine has come to exert an important influence on medicine in this country. It has the largest medical library in the United States next to the Surgeon General's and it probably serves more readers than any other medical library in the world.

The membership of the New York Academy of Medicine is in the area of 2,400. Its annual income from dues in 1946 was $88,000. Yet this organization has an endowment of $4,000,000, and an annual income of more than one-third of a million dollars each year. In the beginning, it did not own its own home, but now it has a magnificent building for meetings, as well as to house its wonderful library.

The New York Academy of Medicine has a group of Committees which function in many ways to assess the temper of the relations between the medical profession and the public. It has done a very important job on this score, not alone in the area of practice, but also in medical education as well.

The New York Academy of Medicine has more than a century of experience. That development obviously could have occurred only in a large metropolitan area like that of New York City. But most important of all, it has had strong and generous men of vision at the helm over long periods of years who have given the Academy distinguished directional leadership.

Our Academy

The Minnesota Academy of Medicine has now been in existence for two-thirds of a century. It came into being, when the State of Minnesota could count only slightly more than one-third of a century in years. In the main, it has been essentially a Dining Club of Professional Men interested primarily in the practice of medicine. It has never taken on the sustained support of any continuing endeavor. We have no home of our own, nor is it necessary that we should have one. We have no library; we have rather meager funds, there being less than $9,000 in our treasury. However, we do have a long tradition of counting amongst our members a large number of distinguished persons in the Specialties of Medicine in the Twin Cities, including also a lesser number of members scattered throughout the State. Anyone who has been long a member of the Academy cherishes memories of evenings spent here with pleasure and profit, chatting and dining with his friends and listening to their presentations.

The character of our programs has changed quite remarkably within the last few years. Up until approximately fifteen years ago, the program was constituted largely from within the membership. As the years have gone by, and especially during the last few years, a rather large proportion of the papers have been given by young men who have done distinguished research in the Medical School of the University of Minnesota. In a sense, this is very fitting. We are all anxious to become alert to the newer developments in medicine. Moreover, we all have an anxiety to become acquainted with young men who are doing significant work in research. It is very proper therefore that the Executive Committee of the Academy during the past few years should have encouraged this trend in our programs. We are all beholden to them for their foresight in lending emphasis to that which is *new* in Medicine.

We are essentially a group of Specialists in Medicine with a primary focus of interest on practice. All of us are aware of the great influence which research has had upon progress in Medicine. The art and the practice of Medicine have been changed for the better considerably through the agency of research.

As the Academy begins now its final third of its first century of existence, we might well contemplate taking on some function beyond that of a Professional Dining Club with an evening's scientific program. Those organizations and individuals, who can point only with pride to their predecessors, find, like the potato vine, that their best portion is underground. Would it not be worthwhile asking the Executive Committee to give consideration and thought to finding some special function which the Academy might take under its protective wing? Through such an agency, the life and influence of the Academy would be perpetuated and transmitted more directly to our successors in a tangible, objective manner. Such a manifestation of appreciation of our opportunities and recognition of our collective obligation to our profession would have the additional advantage of making a contribution to the furtherance of our art and practice.

There are undoubtedly many ways in which such an objective could be achieved. The records of the Academy indicate that Dr. S. Marx White in the November meeting in 1908, two years before he assumed the presidency of the Academy, suggested that the Academy consider the establishment and support of a Fellowship at the University of Minnesota. It is interesting to observe that the following month the membership approved of the suggestion and voted an assessment of $5 per person to support a Research Fellowship Fund at the Medical School. As far as is known, the only temporary occupant of that position was Dr. F. W. Schlutz, who many years subsequently became Professor of Pediatrics at the University. We do therefore have a precedent for such a suggestion.

In 1953, such an annual assessment against each member of the Academy would not go far in the support of a Fellowship. Inasmuch also as we represent all the Specialties of Medicine, it probably would be more proper to consider something which might be shared equally by the Specialties of Medicine. A suitable triennial or quinquennial prize to be given to that person in the United States, whose research in the opinion of the Academy's Committee has given the most important impetus to the furtherance and improvement of medical practice—such an award might become a function of the Academy. However, I am inclined to believe that, however important such a prize in future years may come to be, nevertheless, the administration of such a project would in itself be a very difficult task. Moreover, I am inclined to believe that the support of Scholarship through an annual gift to the Medical Library of the University of Minnesota would have a more telling effect; also that such an endeavor would be more suitable to our purposes.

When Osler came here to give his famous lecture on the campus of the University of Minnesota in 1902, President Northrup announced that the Medical Library of the Medical School had a thousand volumes in its collection. The situation has changed considerably for the better since then, and the Library also has improved correspondingly. If the Academy would take on the responsibility of sponsoring some function served by the Medical Library in a sustained manner, the Academy could well become a Patron of Scholarship in the Medical School. That also would be a function which we could all enjoy and the Academy could come to be a continuing contributor to an important and a living function of this Medical Community.

The New York Academy of Medicine came into being to help increase the confidence of the public in the Profession and to help stamp out the "rampancy of quackery." In the 1940 Constitution of the Academy, the specific purposes of the New York Academy of Medicine are listed as "support of the science and art of medicine, the maintenance of a public medical library, and the promotion of medical health and medical education." It has done its task well.

Nothing in life gives such directional growth to development as does the assumption of a serious purpose. I believe that our own Academy needs such an influence. How else can we attain the stature of importance in this Medical Community which our Founders contemplated so long ago?

Every physician needs breadth of vision which can come only through experience and study. And the true specialist must, in a sense, be a scholar. If he were not, he would not be a specialist. Scholarship must of necessity be an unrelenting and continuous labor. Johann Fichte was one of the early prophets of a budding scholarship in

Germany toward the end of the eighteenth and the beginning of the nineteenth century. Fichte's theme was cultivation of reverence for knowledge and scholarship as the mark of a scholar. I believe that all professions would do well to consider stimulation of scholarship within their provinces of action as an important function of such professional organizations. Fichte differentiated students into two classes, "Die Studierte"—students who have studied and "Die Studierende"—those who study. If it could be said that it were necessary to become classified among "Die Studierende" to become eligible for membership in the Minnesota Academy of Medicine, we would all note within our midst a quickening of interest in scholarship. Alma Mater are words, spoken with tender affection by many an alumnus who may fail to appreciate that these two noble words are synonymous with Foster Mother. If we were to assume the role of foster parent to scholarship in this medical community, we would contribute to our own development, afford ourselves a source of continuing satisfaction and begin an enterprise which one of our own Julian Wests might view with pride, looking back from the year 2000 as did Edward Bellamy's hero of that name in "Looking Backward." Our own Julian West might then say for us: "Well done, members of the Academy in the 50's, all your best is not underground."

A good library can have a tremendous catalytic effect upon the cultivation of superior scholarship. The love of books and the pursuit of learning can vitalize the intellectual life of any organization. Love of books and love of learning go hand in hand. A fine collection of books adds a savor to scholarship which fosters an interest in learning, sharpens the appetite for books and enriches the lives of all who come beneath the spell of scholarship. Every professional library should have its own Arthur Upson room where the professional students can attain a ready acquaintance with the best books of literature in the world. Who, amongst practical men, is in greater need of an acquaintance with good books than physicians? Without a large endowment but with sustained support from year to year, any organization could well become the foster parent of an important Treasure Collection for the Library of the Medical School which could come to have a telling effect upon scholarship in this Community. Why not the Minnesota Academy of Medicine?

TABLE I. POPULATION AND PHYSICIANS IN MINNESOTA AND THE TWIN CITIES

1890 and 1950

	1890	1950	Increase in Population
POPULATION			
Minnesota	1,301,826	2,982,483	230%
Minneapolis	164,738	521,718	280%
Saint Paul	133,156	311,349	
PHYSICIANS			
Minnesota	1,191	3,886	325%
Minneapolis	280	1,141	340%
Saint Paul	201	511	

Should the Academy Enlarge Its Membership?

The accompanying table gives an indication of the change in character in the population and in the number of physicians in the State and in the Twin Cities, during the past sixty years. There obviously has been greater urbanization amongst physicians than in the population as a whole.

There is also probably an even greater concentration of specialists in the Twin Cities now than there was in 1887. Moreover, we have also a rather large family of new specialties, unknown then. Amongst others are: Neurosurgery, Pediatrics, Psychiatry, and Roentgenology, to mention only major new specialties of practice.

It would appear therefore that in 1953, based on an active membership of forty for 1887, it would not be out of line to suggest a steady and gradual increase of our present active membership to 150 persons—approximately a 75 per cent increase in total membership.

The fundamental question that the Academy has to decide is whether it wants to remain essentially a Professional Dining Club or whether it is ready now to assume some of the broader functions implied in the name of glorious origin, Academy. When the German Surgical Society came into being, there was considerable difference of opinion expressed amongst its founders as to what role it should assume. Billroth favored a small informal group in which chatty types of papers would be presented. Langenbeck, however, visualized a large organization with emphasis upon a strong program. Langenbeck's opinion prevailed, and up until World War I, it probably was the strongest surgical organization in the World. If we want this Academy to continue to radiate in this Community, the influence in medicine which our founders had in mind for it, two-thirds of a century ago, we would do well to ponder now Langenbeck's views, as they relate to the nature and responsibilities of our own Academy.

One more suggestion and I am done. I would like to see persons newly elected to membership join us at the *first meeting* following their election. I would remove the clause which makes it mandatory to present a written thesis before a person, elected to membership, can take his place amongst us. In lieu of this provision, he might be asked to submit to the Program Committee an abstract of a paper that he is prepared to present before the Academy. Journals are not in want of materials to print today, and the acceptance of a paper for publication is better left to the discretion of the editors.

It had been my intention to review some of the developments and trends in my own field of surgery which have occurred since I began the study of Medicine thirty-five years ago. However, these are well known to all of you, and many of you will be relieved, I know, to learn that I shall not try your patience by such a recitation now. It would be more proper to attempt to indicate what steps might be taken to resolve some of the pressing problems which confront surgeons today. On that score, I must plead incompetence to assume such a task and remind you that it is far easier to look two centuries back that it is to look five years ahead. A handsome Greek youth, Narcissus by name, is said to have gazed into a fountain and became so enamored of his own beautiful reflection that he pined away, being unable to satisfy his love of his own countenance. Mirror-gazing which engenders feelings of self complacency and satisfaction over our accomplishments is as dangerous an occupation today as it was in the days of the Greek Goddess, Nemesis, who meted out retributive justice to those who were given to too much self-adoration.

While we view with satisfaction the early years of our Academy and speak out in a spirit of grateful thanksgiving for pleasant moments spent together here in good fellowship, let us meditate the question of what legacy we want to bequeath to our successors in the Academy, who, a few decades hence, will help launch this Academy upon its second century. Will they be as satisfied with us as we ourselves have been? While we deliberate upon this matter, may I suggest that you join me in the prayer that our judges will be merciful?

NUTRITIONAL IMPLICATIONS OF SODIUM RESTRICTION

In the preparation of diets restricted to less than 0.5 gm. of sodium daily, alterations from the diet usually considered optimum may be necessary. Thus, a reduction in animal protein and the nutrients usually associated with it may be required, and certain other foods specifically prepared to remove naturally occurring sodium may be added to the diet. These alterations in the usual dietary customs of persons may sometimes compromise optimum nutrition, a matter to be seriously considered by physicians prescribing a low-sodium diet.

Such changes in the diet as the omission of salt for seasoning, using sweet butter, low-sodium bread, and omitting foods naturally high in sodium should involve no nutritional difficulties, except for any attendant decrease in taste appeal. The same is also true for processed foods packed without added sodium salts.

Limitations in the amount of meat and eggs allowed per day will sometimes be necessary, particularly if the daily sodium intake is to be 200 mg. or less. This involves a decrease in protein of high biological value and of the concomitant vitamins of the B complex.

The processing of foods to remove natural sodium may decrease the content of certain other nutrients. Products such as these are appearing on the market in increasing numbers and may be highly desirable because of the low levels of sodium they provide. At present, the extent of the reduction in nutrients other than sodium in these foods is not known, in many instances, but efforts will be made to procure this information and make it available to physicians.

Thus, the physician prescribing a low-sodium diet must weigh carefully the therapeutic benefits to be expected against the consequences of a possible reduction in the intake of essential nutrients. This may be particularly true of persons already malnourished or with conditioning factors such as defects in digestion and absorption or abnormalities in intermediary metabolism.

The Council will consider for acceptance foods packed or prepared without added sodium provided the food is otherwise acceptable and provided the sodium content appears on the label (in milligrams per 100 gm.) in addition to a statement such as "Packed without added sodium." The Council will also consider foods processed to remove naturally occurring sodium. When significant loss of nutrients, other than sodium, is shown to have occurred, a statement to this effect must also appear on the label and detailed information concerning this reduction in specific nutrients must be made available to the Council and to physicians likely to use the product. —JAMA, Council on Foods and Nutrition, August 2, 1952.

A STUDY OF MASSES IN THE RIGHT LOWER QUADRANT OF THE ABDOMEN

J D MORTENSEN, M.D. and J. ARNOLD BARGEN, M.D.
Rochester, Minnesota

WHEREAS there is abundant medical literature pertaining to right-sided lower abdominal pain, little factual or statistical information is available concerning the problem of a palpable mass in the right lower quadrant of the abdomen. Such a lesion is not uncommon in medical practice, and while familiarity with the problems it presents is the rightful domain of all medical practitioners it would seem to be of special importance to surgeons, diagnosticians, gastroenterologists, urologists and roentgenologists. In an effort to obtain reliable statistical information regarding the problem presented by this condition, data on a group of patients who had this lesion and who had been examined and treated at the Mayo Clinic have been collected and studied, these data forming the basis for this communication.

Method and Material

A study was made of the case records of all patients who were examined at the Mayo Clinic during the year 1944 and for whom a diagnosis of palpable mass in the right lower quadrant of the abdomen was recorded. In addition a review was made of the records of 5,879 patients who were examined during the same year and who had a condition which could be a possible cause for a mass in the right lower quadrant of the abdomen. In this manner 468 patients were found to have a palpable mass in the right lower quadrant, and in 455 of these patients the cause of the mass could be considered to be proved, either by operation, postmortem examination or unequivocal clinical findings and subsequent course. This study is concerned primarily with the 455 cases.

In the evaluation of data available from the case records an attempt was made to answer the following questions, thought to be of clinical significance in the handling of patients who have a mass in the right lower quadrant:

1. What is the incidence of such masses in clinic patients and what are the age and sex distributions of patients with this lesion?
2. What lesions may cause such a mass and what is the frequency of occurrence of these lesions?
3. What is the accuracy of the clinical or preoperative diagnosis of the cause of the mass?
4. What methods of examination are most useful in determining the cause of the mass?
5. What is the role of surgery in the management of the patient with such a mass?

TABLE I. AGE AND SEX DISTRIBUTION OF PATIENTS WITH A MASS IN THE RIGHT LOWER QUADRANT OF THE ABDOMEN

	Patients		
Age, years	Male	Female	Total
0 to 9	3	2	5
10 to 19	9	7	16
20 to 29	7	18	25
30 to 39	26	69	95
40 to 49	23	102	125
50 to 59	30	60	90
60 to 69	28	43	71
70 to 79	12	13	25
80 to 89	1	2	3
Total	139	316	455

Results

Incidence, and Sex and Age Distributions.—The 468 patients with a mass in the right lower quadrant of the abdomen comprised 0.36 per cent of the clinic registrants during the year 1944. This agrees rather well with the findings of Butler and Bargen who reported that about 1 of every 200 clinic registrants had such a mass.

It was somewhat surprising to note that women greatly outnumbered men (ratio of 2.3 to 1) (Table I). This is probably explained by the fact that women have two organs in this region not found in men, namely, the uterus and the right ovary, both of which are commonly the site of mass-producing lesions.

The age distribution indicated that this is a lesion of middle age—about two-thirds of the patients studied were in the age group thirty through fifty-nine years (Table I). Extremes in age were three weeks and eighty-six years.

Dr. Mortensen is a Fellow in Surgery, Mayo Foundation, University of Minnesota.

Dr. Bargen is a member of the Division of Medicine, Mayo Clinic, Rochester, Minnesota.

TABLE II

LESIONS FOUND TO BE THE CAUSE OF A MASS IN THE RIGHT LOWER QUADRANT OF THE ABDOMEN

455 CASES

Lesions according to site	Cases		
Gynecologic			169
Uterus		73	
Fibromyoma	59		
Endometriosis	8		
Adenocarcinoma	5		
Fundus adherent to scar of abdominal wall	1		
Ovary		72	
Cystadenoma or simple cyst	26		
Cystadenocarcinoma	20		
Endometriosis	12		
Solid ovarian tumor	9		
Cystic oophoritis and perioophoritis	5		
Fallopian tube		12	
Tubal pregnancy	5		
Chronic salpingitis with hydrosalpinx	4		
Adenocarcinoma	2		
Endometriosis	1		
Pelvic peritoneum		12	
Endometriosis	5		
Adhesions	3		
Pelvic abscess	4		
Gastrointestinal			125
Cecum and ascending colon		71	
Adenocarcinoma	56		
Fecal mass in cecum	7		
Actinomycosis	3		
Tuberculous typhlitis	2		
Chronic ulcerative colitis	2		
Lymphosarcoma	1		
Ileum		29	
Regional enteritis	22		
Ileocolic intussusception	4		
Tuberculous ileitis	3		
Descending and sigmoid colon		11	
Adenocarcinoma	6		
Diverticulitis	4		
Chronic ulcerative colitis	1		
Transverse colon		9	
Adenocarcinoma	6		
Chronic ulcerative colitis	2		
Lymphosarcoma	1		
Appendix		4	
Acute appendicitis	2		
Mucocele	2		
Stomach		1	
Adenocarcinoma	1		

Lesions according to site	Cases	
Renal		74
Polycystic disease	17	
Hydronephrosis	16	
Ectopic or nephroptotic kidney	14	
Normal palpable kidney	10	
Renal cyst	7	
Perinephritis or perirenal abscess	4	
Carcinoma (Wilms', hypernephroma)	3	
Palpable horseshoe kidney	2	
Renal tuberculosis	1	
Intra-abdominal		24
Peritoneal carcinomatosis	12	
Appendical abscess	6	
Metastatic lesion of mesenteric node	2	
Mesenteric cyst	1	
Tuberculous peritonitis	1	
Peritoneal endometriosis	1	
Internal hernia	1	
Abdominal wall		20
Sinus tract of fecal fistula	10	
Incisional hernia	4	
Lipoma	2	
Endometriosis	3	
Desmoid	1	
Inguinal region		16
Cryptorchidism	9	
Metastatic lesion of inguinal node	3	
Incarcerated inguinal hernia	3	
Hydrocele of canal of Nuck	1	
Urinary bladder		8
Distended (obstructed) bladder	3	
Adenocarcinoma	3	
Diverticulum	2	
Retroperitoneal		7
Malignant lymphoma	3	
Aortic aneurysm	2	
Iliac aneurysm	1	
Abscess	1	
Liver		6
Riedel's lobe	2	
Cysts	2	
Metastasis	1	
Cirrhosis	1	
Miscellaneous		6
Hydrops of gallbladder	2	
Carcinoma, prostate	2	
Carcinoma, head of pancreas	1	
Osteochondroma, ilium	1	

Etiologic Factors.—The lesions responsible for the masses in the right lower quadrant of the abdomen are indicated in Table II.

The sites of the disorders causing a palpable mass, as determined by study of the 455 case records, were divided into three groups: (1) the common sites, (2) the occasional sites, neither common nor rare, and (3) the unusual or rare sites. Two hundred and ninety patients (63.7 per cent) had a mass in one of four organs, namely, the uterus, the right ovary, the right kidney, and the cecum and ascending colon. Neoplasms produced most of the masses in these organs, although hydronephrosis and malposition accounted for many of the palpable renal masses. Each of these common sites accounted for about 15 per cent of the masses studied.

In the group of occasional sites, lesions of the peritoneum were the most common, inflammatory lesions and carcinomatosis each causing about half the peritoneal masses. Lesions of the terminal part of the ileum accounted for twenty-nine of the masses, regional enteritis being the most common such lesion. The mass was located in the abdominal wall in twenty cases. Less common sites included the right inguinal canal, the right fallopian tube, and the descending and sigmoid colon. The group of occasional sites accounted for 121 (26.6 per cent) of the 455 cases. Each organ in this group was the site of between 2 and 8 per cent of the masses studied.

In the group of unusual sites there were eleven organs, each harboring a palpable mass in less than 2 per cent of the cases. Collectively these organs accounted for forty-four (9.7 per cent) of the masses. Organs or tissues in this group of unusual sites included the transverse colon, urinary bladder, retroperitoneal tissues, liver, appendix, mesentery, gall bladder, prostate, pancreas, stomach and ilium.

The lesions producing the right lower quadrant masses in these 455 cases may be classified, according to pathologic nature of the lesions, as follows: malignant neoplasms, 128 cases (28.1

per cent); benign neoplasms, 112 cases (24.6 per cent); inflammatory lesions, 98 cases (21.5 per cent); mechanical or structural disorders, 60 cases (13.2 per cent); and developmental or degenerative disorders, 57 cases (12.6 per cent). It can thus be seen that neoplasms (benign and malignant) accounted for more than half of the masses.

Accuracy of Clinical (Preoperative) Diagnosis.—Correct clinical or preoperative recognition of the cause of the mass was made in 398 (87.5 per cent) of the cases studied. In only fifty-seven (12.5 per cent) of the cases was the postoperative diagnosis significantly different from the clinical or preoperative diagnosis. In most of the latter cases the preoperative diagnosis was simply mass in the right lower quadrant of the abdomen, and the operation was undertaken as an exploratory procedure. In seventeen of these cases, it would seem likely that complete preoperative study could have established the correct clinical diagnosis. However, in most such cases surgical treatment would have been indicated anyway. In these seventeen cases, the barium enema and excretory urography were the procedures most often omitted from the preoperative study. In twenty-seven cases, all appropriate diagnostic procedures were carried out but an accurate and definitive preoperative diagnosis was still not possible, usually because the results of the tests were not entirely diagnostic, being inconclusive or giving an indeterminate diagnosis. The pelvic examination accounted for twenty-two of these indeterminate examinations, urography for four, and the examination with barium enema for one. In thirteen cases (2.9 per cent), the cause of the mass was of such a nature that correct preoperative diagnosis was probably not possible or practical, these being the cases in which exploratory operation was necessary in order to establish a diagnosis.

Methods of Preoperative Diagnosis.—To investigate the value and reliability of various diagnostic measures in revealing the cause of a mass in the right lower quadrant each case record was studied to determine in so far as possible which tests were actually utilized and which gave helpful evidence pointing to the correct preoperative diagnosis. The methods of examination were then classified as (1) diagnostic procedures, that is, those examinations which resulted in positive identification of the causative lesion, or (2) contributory procedures, that is, those tests or examinations which, while not diagnostic in themselves, gave evidence which contributed to the establishment of the correct diagnosis. In 226 cases (49.7 per cent) a single diagnostic procedure resulted in the correct identification of the causative lesion while in the remaining 229 cases (50.3 per cent) the correct diagnosis depended on collection and evaluation of the results of a number of tests and examinations, none being diagnostic but each contributing helpful evidence.

Roentgenographic examination of the colon by means of a barium enema revealed the correct cause of the mass in ninety patients, while urographic roentgenography resulted in identification of the cause of the mass in forty-nine cases and bimanual pelvic examination resulted in recognition of the cause in forty-three cases. Other diagnostic procedures resulting in positive identification of the cause of the mass in smaller numbers of cases included roentgenologic examination of the upper part of the gastro-intestinal tract, various bacteriologic smears and cultures, digital rectal examination, physical examination of the mass itself, cystoscopy, physical sigmoidoscopy, cleansing enema, cholecystography, urethral catheterization and roentgenography of the bony pelvis.

The medical history of the present illness was the most useful contributory diagnostic procedure, being an important factor in preoperative recognition of the cause of the mass in 352 (77.4 per cent) of the patients studied. The general physical examination was helpful in 330 cases (72.5 per cent) and examination of the mass itself in 268 cases (58.9 per cent). The pelvic and rectal examinations were often helpful, and the past medical history not infrequently yielded important diagnostic evidence.

Management of the Patient.—Three hundred and ten (68.1 per cent) of the patients with a mass in the right lower quadrant underwent surgical treatment for this lesion while the other 145 patients (31.9 per cent) were managed medically. Definitive surgical treatment, aimed at cure of the patient, was undertaken in 228 patients (50.1 per cent of those with a mass and 73.6 per cent of those who underwent operation). Definitive medical treatment was given in forty-eight patients (10.5 per cent of all patients studied and 33.1 per cent of those not operated on). Palliative surgical procedures were carried out in thirty-eight patients (8.4 per cent of all patients with a mass and 12.3 per cent of the patients undergoing operation), and medical palliation was utilized in the management of fifty-two patients (11.4 per cent of all patients studied and 35.9 per cent of those managed medically). No treatment was undertaken in forty-five patients with nonsurgical lesions and in forty-four patients who underwent exploratory operation.

The nature of the operation finally performed on the 124 patients for whom only an exploratory procedure was scheduled seemed especially significant. It should be pointed out that in most of these patients the cause of the mass was recognized preoperatively, the operation being listed as an exploratory procedure because the operability of the lesion was not known. In approximately a third of the 124 exploratory operations definitive therapy was carried out, in a third palliative procedures were done, and in a third the surgical exploration resulted in establishment of the diagnosis only, no surgical therapy being attempted.

Comment

Causative Lesions.—The surprisingly high incidence of uterine fibromyoma and cystic lesions of the ovary as causes of masses in the right lower quadrant of the abdomen most certainly is related to the common occurrence of these lesions rather than to their location or abdominal palpability. While most uterine fibromyomas and ovarian cysts cause pelvic masses and are not palpable abdominally, these lesions are so common that the 2 to 3 per cent which are palpable in the right lower quadrant of the abdomen constitute a relatively high percentage of the masses which occur in this region.

Perhaps our most significant observation is the fact that masses in the right lower quadrant may be caused by many different disorders, the most common cause representing less than 15 per cent of the patients presenting a mass in this location. Seventy-four different disorders were found as causes for the 455 masses, and these lesions were located in twenty-one different anatomic structures. Such data emphasize the importance of objective, open-minded approach to the diagnostic study of a patient presenting a mass in the right lower quadrant. Such patients must not be categorized but each must be studied individually. Many possible causative disorders must be kept in mind and such diagnostic examinations must be carried out that even relatively uncommon lesions are routinely considered and ruled out as diagnostic possibilities. Certainly the diagnostic acumen of the examiner is heavily taxed in the study of a patient with such a mass.

Preoperative Diagnostic Accuracy.—Another important observation derived from the above data is the relatively high degree of accuracy with which the cause of a mass in the right lower quadrant of the abdomen can be determined clinically. This indicates that, commendable as it may be, the present-day contention of many physicians that "no mass is a good mass" and that every lump or swelling should be explored by biopsy or surgical exposure can hardly be condoned currently. Such an attitude not only encourages diagnostic laxity and fails to recognize or fully utilize modern diagnostic facilities but, more seriously, may result in ill-advised, useless surgical treatment which might have been avoided or modified had the surgeon been more energetic in the preoperative examination of his patient.

Thirty years ago a textbook[6] on diagnosis carried the statement that "diagnosis (of abdominal masses) is largely by exclusion, seldom direct . . ." and "the probable nature of the abdominal tumor is a matter of statistics." Twenty years ago an eminent surgeon[1] wrote: "As far as tumors are concerned, the abdomen is indeed a temple of surprise, and it is by our diagnostic humiliation when the abdomen is opened that we learn." These were accurate descriptions of diagnostic reliability when they were written, but fortunately they can now probably be revised. While it is unquestionably worth while, even essential, that we realize our diagnostic limitations, by the same token there is folly in failure to recognize and utilize refinements in technique or new procedures that overcome to some extent previously insurmountable obstacles to diagnostic accuracy. Whereas reliance on surgical exploration for diagnosis of most masses in the right lower quadrant of the abdomen was once necessary, preoperative direct and positive diagnoses of the causes of many such masses are now being made regularly by clinicians, roentgenologists and urologists who understand how and when to use modern diagnostic procedures, relatively few patients being submitted to operation for diagnostic purposes.

Furthermore, present-day methods of treatment of the causes of masses in the right lower quadrant of the abdomen require rather specific and accurate knowledge concerning the mass. Recognition of the organ in which the mass is located often suggests the most accessible route to the mass, either with medications or by surgical attack. Identification of the specific etiologic agent causing an inflammatory mass may dictate the chemotherapeutic or antibiotic agent which should be used to eradicate the infection. The value of surgical exploration and its safety are greatly enhanced if the intimate relationship of the mass to the bowel is recognized preoperatively and effective preparation of the colon has been carried out, enabling the surgeon to open, resect or anastomose bowel without danger of peritonitis. Recognition that a mass in the right lower quadrant is without doubt retroperitoneal and is approachable through an extraperitoneal lumbar incision may offer the patient an operation with half the mortality that is commonly associated with the transperitoneal abdominal exploration of a retroperitoneal mass which would most likely be utilized if the location of the mass had not been recognized preoperatively.

Thus, current standards of medical practice would seem to indicate that, except under unusual circumstances, a simple diagnosis of "mass in the right lower quadrant of the abdomen" should not be considered adequate basis on which to recommend specific therapy or offer a prognosis, much less to advise or undertake surgical intervention, at least until the patient has been carefully examined by modern diagnostic methods in attempts to gain as much information as possible about the mass. Such a conclusion has recently been expressed by Engel.

Methods of Examination.—The data concerning the value of various diagnostic measures in determining the cause of a mass in the right lower quadrant admittedly are not entirely objective and represent only a crude attempt to show statistically a problem of interpretation. However, the point seems adequately demonstrated that such examinations as roentgenography of the colon with barium enema, excretory urography, and careful bimanual pelvic examination should be carried out preoperatively on every patient with a mass in the right lower quadrant, the cause of which has not been accurately identified. The overwhelming number of patients who have a mass in the right lower quadrant and whose clinical history, general physical examination, and examination of the mass itself have contributed importantly toward establishment of the correct preoperative diagnosis should be ample evidence of the necessity for careful and painstaking consideration of these diagnostic procedures for every patient with such a lesion.

Management.—Since only about two thirds of the masses studied were handled surgically it would seem unwise to assume that every patient with such a lesion needs an operation. The disappointing results of exploratory operations for a mass in the right lower quadrant of the abdomen (that is, only one in three patients is materially benefited from the operation) is strong evidence that accurate preoperative clinical diagnosis should be striven for diligently before surgical exploration is recommended.

Summary and Conclusions

Data derived from the records of 455 patients with a palpable mass in the right lower quadrant of the abdomen would seem to justify the following conclusions:

1. Masses at this site may be caused by a wide variety of lesions located in any of twenty or more anatomic structures. The four most common causative lesions, accounting for about 60 per cent of the masses studied were those of the uterus, the right ovary, the right kidney, and the cecum and ascending colon. Neoplasms were accountable for most of the masses in these organs. The remaining 40 per cent of the masses were caused by seventy different types of lesions, each of which occurred in less than 5 per cent of the patients with right lower quadrant masses.

2. An accurate clinical (preoperative) diagnosis of the cause of such a mass should be conscientiously attempted in every instance, and it probably can be established in from 85 to 90 per cent of the patients who are thoroughly studied.

3. Diagnostic methods and procedures most often giving the direct and positive clinical diag-

ANALYSIS OF TUBERCULOSIS CASE REGISTERS IN MINNESOTA

D. S. FLEMING, M.D., M.P.H.
Minneapolis, Minnesota

IN RECENT years, mortality figures for tuberculosis have given a distorted picture of the problem of this disease in Minnesota, leading to an overly optimistic impression that tuberculosis no longer is a serious burden. On the other hand, figures of new cases reported each year, while indicating no marked drop comparable to reductions in deaths, have not been adequate to picture the continuing load of tuberculosis victims that accumulate over the years. Since tuberculosis is a chronic disease, subject to reactivation and breakdown over long periods of time, other measurements than annual case and death rates are required to indicate the problem.

Such measurements are available in Minnesota from reports submitted to the State Health Department by a number of health agencies which operate case registers as a means of providing health supervision of all known cases of tuberculosis within their jurisdictions.

The State Health Department maintains a Central Case Record System consisting of a master index of all reported tuberculosis cases and deaths in Minnesota together with a current file of all administratively active cases, and a closed file of all cases considered administratively inactive. This system functions with local case registers through the medium of information interchange.

The local case registers presently functioning in Minnesota include that of the Minneapolis Health Department for cases in Minneapolis City; the register of the St. Paul Bureau of Health for cases in St. Paul City; and the register of Nopeming Sanatorium for cases in St. Louis County, including Duluth City. The State Health Department is attempting to decentralize its tuberculosis records system by setting up a case register in each of the Department's eight District offices to cover

ANALYSIS OF TUBERCULOSIS CASE REGISTERS

December 31, 1952

I. Numbers of cases in current register

	Minneapolis City	St. Paul City	St. Louis County	Rest of State	Total
Pulmonary	1,677	1,339	2,440	5,531	10,969

Total	1,956	1,272	2,460	4,832	10,520

the counties making up each District. At present three such district registers are operating. The Department in addition maintains separate registers for Indian cases, and cases in state institutions.

Information about a case varies in completeness in different registers, dependent somewhat on the purpose of the register. In general, however, each case record includes such basic data as name, age, sex, address, the type of tuberculosis diagnosed such as pulmonary or non-pulmonary, the extent of the lesion, the clinical status whether active, arrested, or inactive, and the hospitalization status.

By analyzing the registers described above, it is possible to assemble on a statewide basis much valuable information regarding the total load of cases of tuberculosis. Such analysis has been made on three occasions, at six-month intervals, as of

OBSCURE FEVER OF HYPERNEPHROMA

LYLE V. KRAGH, M.D., HAROLD H. JOFFE, M.D., ARTHUR H. WELLS, M.D.,
and RALPH J. ECKMAN, M.D.
Duluth, Minnesota

IT IS our purpose first, to report a case of proven hypernephroma in which the only outstanding sign and symptom was fever, and secondly, to review the cases of hypernephroma at this institution from 1936 through 1952.

Case History

This forty-two-year-old displaced person, spontaneously delivered her second child on March 21, 1952. The puerperium was complicated by a persistent afternoon fever as high as 100.8 degrees. The physical examination was negative. A heterophile antibody test, urinalyses, urine smears and cultures were likewise negative. The red blood cell count varied from 3,240,000 to 4,080,000 with 10.5 grams of hemoglobin. The white blood cell count varied from 9,250 to 11,200 with 88 per cent neutrophils. A chest plate revealed bilateral apical fibrocalcific scarring. The patient left the hospital against advice before an adequate evaluation as to the cause of the fever could be accomplished.

The patient was readmitted on May 22, 1952, with complaints of fever, weakness and loss of appetite. A history of vaginal bleeding for about five days after her last discharge from the hospital was obtained. This ceased spontaneously. There was no history of abnormal menses. The patient continued to have an afternoon elevation of temperature during this hospitalization, averaging around 100.4 degrees, associated with sweats. Physical and pelvic examination revealed nothing of note. Urinalyses were normal. The red blood cell count varied from 3,200,000 to 3,610,00 with 8.8. to 9.1 grams of hemoglobin. The white blood cell count ranged from 6,250 to 10,800 with 74 to 83 per cent neutrophils. The red cell sedimentation rate was 126 mm. per hour. Several examinations of the stools revealed no occult blood, ova or parasites. Urine smears and cultures were negative, for pathogenic bacteria, including acid-fast organisms. Six blood cultures and a Kline test were also negative. Sputum concentrates and gastric cultures failed to reveal acid-fast bacteria. The Mantoux test was three plus. The blood urea nitrogen and sugar were normal. The icterus index was 10.2 units but three different liver flocculation tests were negative. No malaria parasites were found. Agglutination test for melitensis, typhosus and tularensis were negative. A repeat heterophile antibody test was negative and bone-marrow examination revealed some increased erythroid activity. A repeat chest plate when compared to the previous film and one taken at the displaced person's camp, revealed no change. The fever did not subside on penicillin therapy and the patient was transferred to a nearby sanatorium for further evaluation as to the activity of the bilateral apical scarring.

At the sanatorium, a repeat pelvic and bone marrow examination were negative. A frog-test for a post-patrum malignancy was likewise negative. The sputa, gastrics and urine were negative for tubercle bacilli on culture and guinea pig inoculation. Several repeat blood cultures revealed no growth.. The red blood cell count was 3,020,000 with 8.2 grams of hemoglobin. The white blood cell count was 12,950 with 85 per cent neutrophils and the red cell sedimentation rate was still elevated at 107 mm. per hour. In spite of no radiologic or laboratory evidence of tuberculous activity, the patient received both streptomycin and para-amino-salicylic acid. The daily fever continued, varying from 99 to 102 degrees. An x-ray of the pelvis, lumbar spine, upper gastrointestinal series and barium enema revealed no abnormalities. An intravenous pyelogram on July 28, 1952, revealed a peculiar shadow on the right side which could not be accurately evaluated because of overlying gas-filled bowel. A retrograde pyelo-uretogram was planned but the patient refused to remain in the sanatorium any longer.

The last admission was on September 9, 1952, and the patient was still running a fever. Further extensive laboratory and radiologic studies were negative except for the probable presence of a retroperitoneal mass on a repeat retrograde pyelogram.. An exploratory laparotomy on September 18, 1952, revealed a tumor of the lower pole of the right kidney and a nephrectomy was done.

The 8 cm. in diameter nodular tumor was friable and yellow with areas of cystic degeneration and hemorrhage. The renal vein was not invaded. Microscopically, it was made up of large polyhedral cells with clear vacuolated cytoplasm, typical of adenocarcinoma of the kidney. On the first postoperative day her temperature dropped to normal for the first time in six months and remained normal until her discharge from the hospital on September 25, 1952.

Tumors of the kidney, like syphilis and tuberculosis, are the great mimics in medicine and produce the clinical picture of a variety of diseases.[5] The diversity of symptoms have been attributed to: (1) pressure on adjacent structures; (2) necrosis or hemorrhage in the neoplastic tissue; (3) local extension or metastases and (4) absorption of toxic products.[10,16]

At this institution a total of forty-two cases of adenocarcinoma of the so-called hypernephroma type were diagnosed either by surgical specimens or necropsy examinations in the period from 1936

From the Department of Pathology, Saint Luke's Hospital and Nopeming Sanatorium, Duluth, Minnesota.

TABLE I. SEX INCIDENCE

Sex	Number	Age Range	Average Age
Male	18	39-73	60.4
Female	17	37-84	60

TABLE II. SYMPTOMS

Sympton	Number	Percentage
Hematuria	18	51.4
Palpable mass	7	20.0
Back pain	2	5.7
Chest pain	2	5.7
Bilateral strabismus	1	2.8
Skeletal fracture	1	2.8
Anemia	1	2.8
Shoulder pain	1	2.8
Cough	1	2.8
Fever	1	2.8

through 1952. Seven of the cases were considered incidental to more important necropsy findings. The sex ratio and age of the thirty-five cases is shown in Table I. There was no statistical difference as to which kidney was involved. All of the thirteen necropsy cases had generalized metastases. In the remainder of twenty-two surgical cases, the renal vein was invaded in only five instances with three of these cases coming to necropsy after an average of two years.

The usual symptoms of hematuria, palpable mass and pain is a familiar triad.[2,6,20] In a combined series of 230 cases[2,20] hematuria was present in 79 per cent; palpable tumor in 53.5 per cent and pain in 43.9 per cent. In our series of thirty-five cases, hematuria occurred in 51.4 per cent; palpable tumor in 20 per cent and lumbar or back pain in 11.4 per cent of the cases (Table II).

The occurrence of fever in the course of malignant disease or as a result of an infectious complication has long been known.[1,4,7,8,11,16,20,21] The incidence of fever as a prominent symptom with one or more of the classical findings varies from 1.25 to slightly over a 11 per cent.[4,6,16,17] There was no case in a combined series of 364 cases[2,8,17,20] in which fever was the sole prominent finding. In our present review of the literature only sixteen cases could be found in which fever was the sole presenting symptom.[3,4,9,10,15,16,18,19,21]

The hypernephroma type of adenocarcinoma of the kidney tends to grow slowly and the classical symptoms of hematuria, palpable mass and pain, may be late manifestation.[5,10] The first symptom may frequently be due to metastases.[5,10,13] In a review of ninety-two clinical and necropsy cases, the first symptom was due to either metastases or local extension in 41 per cent of the cases.[5] In our series, the first symptom was due to metastases in six cases with pleural effusion in three; shoulder pain; bilateral strabismus and spontaneous fracture in one case each, for an overall percentage of 17.1.

The diagnosis of renal carcinoma with fever as the sole presenting symptom is difficult and often missed because these tumors frequently produce no defect of either the pelvis or calyces. These tumors have a tendency to grow laterally and the only pyelographic change may be a displacement or an increase in the kidney size.[7]

The possibility of a hypernephroma should be kept in mind in any case of obscure fever. If the fever does not subside after nephrectomy, metastases should be suspected.[16]

Summary

1. A case of unexplained fever of six months' duration is reported in which a nephrectomy for adenocarcinoma of the kidney was followed by a return of the temperature to normal.

2. In our series of thirty-five cases, hematuria occurred in 51.4 per cent; palpable mass in 20 per cent and either back or chest pain in 11.4 per cent.

3. The first presenting symptoms on the basis of metastases occurred in 17.1 per cent of the cases.

Laboratory Aids to Medical Practice

Sponsored by
The Minnesota Society of Clinical Pathologists

A RAY OF HOPE FOR A CHANGE

JAMES S. MC CARTNEY, M.D.
Department of Pathology, University of Minnesota Medical School
Minneapolis, Minnesota

MINNESOTA needs a change from its archaic coroner system to a modern plan for the investigation of deaths that presently do or should come under the jurisdiction of the coroner. That this is so was ably set forth by Victor Cohn and Charles W. Bailey in their recent series of articles entitled "Hidden Murder," in the *Minneapolis Morning Tribune*.

For many decades Minnesota has had as coroners persons who are elected for a short term of office. To qualify for the office of coroner one needs no background or foundation in medicine, and no training in such procedures as investigation of death, gathering of evidence, identification, photography, chemistry or toxicology, but only the necessary filing fee and the carrying on of a more or less vigorous election campaign.

Consequently, the roster of coroners in the eighty-seven counties of Minnesota is made up of individuals from all walks of life who represent a great many different occupations. A survey shows that about half the coroners are physicians. Inquiry will reveal that most of these physicians are coroners not because they want the job but actually because of a sense of civic duty.

While, of necessity, physicians have training in disease, few have more than a little training in pathology and most of them no training in forensic or legal medicine. Most of them try to do a good job as coroner but must necessarily work under a great handicap because of the demands of the practice of medicine. Surely the fee of $10.00 per day for investigating a death is hardly an inducement to undertake the job. The coroner or his deputy must be available twenty-four hours a day the year around, as fatal accidents, murders and violent deaths occur at all hours. That no valuable clue may be lost, destroyed or overlooked requires investigation of the scene without delay. A physician-coroner is not always immediately available.

A busy practitioner does not have the time to acquire the collateral information and training he needs to discharge fully his duties. If the physician-coroner is lacking in training in the various phases of forensic medicine, how much greater is the handicap of the coroner who has no scientific training whatsoever?

It is in recent sudden or violent death that the trained investigator has the best chance to gather pertinent and important evidence. But if the body and the place of death have been disturbed by ignorant or careless persons, be they officials of the law or curiosity seekers, then the problem of gathering evidence to solve the problem is made enormously more difficult. It may be impossible to obtain truthful photographs, measurements by triangulation or fingerprints, all of which may be of extreme importance. The innocent may be accused wrongfully, the guilty may escape or a dependent family may lose insurance benefits.

It is in deaths that have occurred a long time before discovery, particularly when decomposition has taken place or attempts have been made to cover up a crime or destroy evidence, that the investigator is really put on his mettle to reconstruct the circumstances and to determine the means and cause of death. At such times the responsible official needs to have at his command such experts in many different fields as skilled pathologists, photographers, roentgenologists, toxicologists, immunologists, botanists or anthropologists, not to mention experts in obtaining latent fingerprints and experts in ballistics and fabrics.

Obviously such experts are not available in every county in Minnesota. If, however, a statewide medical-examiner system could be set up, it would be possible to develop machinery so that an early, if not an immediate, investigation could be made. Undoubtedly many unsuspected violent deaths would be found. Exact causes of death could be determined and guesswork to a considerable degree eliminated. On a state-wide basis such a system would probably cost less than the present inefficient coroner system.

For a long time many physicians have been aware that the present coroner system is anything but satisfactory. A committee dealing with this subject has been in existence for many years. This committee of the Minnesota State Medical Association has done a great deal of work on this subject, gathering information on laws in other states and determining how the medical-examiner system has worked out where it has been established. Not long ago Dr. C. E. Proshek, the chairman, called a meeting of the committee and invited representatives of the legal profession, the sheriffs, the Minnesota State Board of Health, the pathologists, the insurance companies and the legislature to talk over this problem.

It now appears, according to a recent item in the *Minneapolis Star*, that an interim commission of the legislature has been proposed to study the question of the medical-examiner system versus the coroner system.

This is indeed a ray of hope that we may now be on the way to replacement of the worn-out coroner system with a medical-examiner system in the best sense of the word, namely a medical examiner appointed because of ability and training and with indefinite tenure.

This is the fifth in a series of editorial reports sponsored by the Minnesota Society of Clinical Pathologists and designed to emphasize ways in which laboratory methods may aid in the practice of medicine. The editorial committee of the society is glad to present this timely comment from Dr. McCartney, who is one of the leaders in the movement to bring up to date the investigation of sudden death in Minnesota.

Wherever communities have replaced the old-fashioned coroner system with the modern scientific methods incorporated in a medical-examiner system, the benefits accruing to such communities have been undeniable. Pathologists are proud of the part they play in the detection of crime and in the solution of problems concerned with sudden death. The time has come for Minnesota to discard the outmoded coroner system, under which you can get away with murder.

This presentation again emphasizes the multifaceted character of the modern laboratory physician. Practicing physicians are urged to utilize more extensively the services of their colleagues in pathology. The editorial committee, consisting of Dr. Arthur H. Wells of Duluth and Drs. Arthur H. Sanford and George G. Stilwell of Rochester, welcomes comments and suggestions regarding this series of reports.

Rochester, Minn.

A STUDY OF MASSES IN THE RIGHT LOWER QUADRANT OF THE ABDOMEN

(Continued from Page 485)

nosis of the cause of such a mass are roentgenography of the colon with barium enema, urographic roentgenography, bimanual pelvic examination, and careful physical examination of the mass itself. However, the diagnosis can be established in only about half the cases by one of these direct diagnostic procedures, making it necessary in an equal number of patients to evaluate carefully the findings and results of a battery of routine tests and examinations, each contributing evidence but not being diagnostic in itself. The most useful of these contributory diagnostic measures are the history of the present illness, the general physical examination, the examination of the mass itself, bimanual pelvic examination, rectal examination, and inquiry into the past medical history.

4. While surgical treatment is indicated in about two thirds of patients with a mass in the right lower quadrant of the abdomen, clinically diagnosable nonsurgical lesions cause such a mass commonly enough that routine surgical exploration without thorough preoperative attempts at diagnosis must be decried as unsound and not commensurate with the highest standards of modern medical practice.

President's Letter

THE DELEGATES DECIDE

A virtual about-face was made by the House of Delegates of the American Medical Association on March 14.

Meeting in special session in Washington, D. C., to act on President Eisenhower's Reorganization Plan No. 1, the delegates committed the American Medical Association to official support of the new Department of Health, Education and Welfare. The delegates were honored to hear President Eisenhower, Senator Taft, and Congressman Walter Judd, who spoke in favor of the plan.

But support was not immediate, nor did it come easily. The delegates undoubtedly remembered the Association's long stand for a separate department of health, with a doctor of medicine at its head. But after many deliberations, some of them heated, a decision was made to accept the reorganization plan, with reservations.

The plan itself transfers all former activities of the Federal Security Administration to the new department, elevating the secretary to cabinet status. The secretary will have a Special Assistant for Health and Medical Care who will be a doctor of medicine with no previous governmental experience, but with wide experience in the field of medicine.

Granting that the plan was not what the delegates originally wanted, the general feeling was that it is a step in the right direction, that it is basically a good plan—that with proper support and co-operaion, it will work well.

The reservation made by the House was this: "the Association reserves the right to make recommendations for amendment of the then existing law or to press for the establishment of an independent Department of Health, if the present plan does not, after a sufficient length of time for development, result in proper advancement in and protection of health and medical science and in their freedom from political control."

Dr. Louis H. Bauer, president of the American Medical Association, makes this conclusion: "I believe (the resolution) was a wise decision, in view of all the aspects of the situation . . . we shall be embarking on a new sea of adventure, and I believe the medical profession of the United States can wield a constructive influence on the health of the American people. I am sure that we shall have every possible co-operation from Washington. The address of the President of the United States to the House of Delegates certainly assured us of that."

President, Minnesota State Medical Association

POLIO CULTURE

OF CONSIDERABLE local interest should be the research conducted at the University of Minnesota by Drs. Jerome T. Syverton and William F. Scherer. Associated in this investigative work in connection with poliomyelitis and supported by the March of Dimes has been Dr. George O. Gey of the Department of Surgery of Johns Hopkins University. They have shown that cultures of the polio virus can be isolated from blood or stool of infected individuals by employing a medium of human cells in tissue culture.

The cells found by these investigators to be well suited as a culture medium for this virus were obtained from a human carcinoma of the cervix removed at the Johns Hopkins Hospital in 1951 and propagated in serial test tube cultures since that time. The polio virus grows rapidly in this cellular medium. Within 72 hours the amount of polio virus has increased about a million times. The investigators have been searching for a non-nervous tissue for continuous cultivation since 1949. The present stable strain of human cell promises to provide a culture medium for practical use in the fight to control poliomyelitis.

This cancer cell tissue apparently can be kept growing indefinitely in serial test-tube cultures. Since the cells quickly reveal characteristic damage from infection by the polio virus, they can be used as an index of virus growth. So hardy are these cancer cells in culture that the tubes containing cells can be shipped long distances without losing their value for culture growth. In addition to the use of this medium for detecting polio infection it may be used to determine an individual's immunity to any of the three types of polio.

AMERICAN FEDERATION OF MEDICAL CENTERS

RECENTLY a proposal was made by Dr. Edgar H. Norris to revolutionize the provision of medical care in this country by enlisting the assistance of businessmen in establishing central clinics in centers of population (more than one in the larger cities), to provide medical care of a standardized type through insurance.

Dr. Edgar H. Norris was a graduate of the University of Minnesota Medical School in 1919, and was associated with Dr. Arnold Schwyzer of Saint Paul in the practice of surgery from 1919 to 1922, when he formed a partnership with the late Dr. Frederick H. Neher. In 1924, he established his own medical group and practiced until 1930, when he became ill and moved to Mexico to spend some five years in recuperation. During this period he is said to have developed his plans to revolutionize the provision of medical care in America. In 1935, he was a fellow in Pathology at the University of Minnesota Medical School and in 1938, was made Professor of Pathology at Wayne University College of Medicine at Detroit. In 1945, he became a Research Associate at Massachusetts General Hospital in Boston as an associate of Dr. Tracy B. Mallory. He now lives in Detroit and has founded the American Federation of Medical Centers Plan for supplying complete medical, hospital, surgical, and dental care at low cost to individuals on a voluntary prepaid basis.

Not having access to Dr. Norris' book,* we did not feel qualified to pass judgment on his ideas. We were more than a little interested however to read Dr. Frank G. Dickinson's critical analysis** of Dr. Norris' book which appeared in the *Journal of the American Medical Association* of Februray 7, 1953. Dr. Dickinson has a Ph.D. degree and is Director of the Bureau of Medical Economic Research of the American Medical Association and his opinions merit consideration.

In brief, Dr. Norris' scheme is to give businessmen a large degree of control over medical care in order, in his opinion, to make that care more efficient. Medical care is to be provided by a single institution in each community in which two-thirds of the doctors are to be general practitioners and one-third specialists. Competition between physicians is to be eliminated. He wants to scrap the present system of private practice and substitute a form of panel practice with restrictions on the patient's free choice of physicians, the cost to be met by an insurance payment of $100 per family. The scheme envisions all the doctors voluntarily joining groups to take part in a standardized type of practice and be paid by insurance companies.

---

*Norris, E. H.: Medicine Rededicated, Health by Community Enterprise. Detroit: American Federation of Medical Centers (limited private printings).

**Dickinson, Frank G.: The Norris panacea. J.A.M.A., 151:511 (Feb. 7) 1953.

As the title of Dr. Norris' book—Medicine Rededicated—infers, his scheme is intended to bring the millenium and solve all problems of medical care in our country. He infers that medical care today is a hodge podge of inefficiency and he does not give due consideration to the great progress that has been made in the past thirty years particularly in the provision of medical care in our country.

We agree with Dr. Dickinson that medical care cannot be furnished as other commodities and furnished by big businessmen but that personality as well as skill is still a valuable component of medical service. We agree that the profession would not voluntarily adopt Dr. Norris' plan of practice and that governmental authority and dictation would be necessary to accomplish such a revolution. While we admit there is room for improvement in the provision of medical care we believe that this will be accomplished better by evolution than by revolution.

CHEMOTHERAPY IN TUBERCULOSIS

ONE YEAR ago reference was made in these columns* to a new antituberculosis drug, isonicotinic acid hydrazide, which had been given considerable publicity in the lay press. This had followed the premature publication in the New York newspapers of investigational work then being carried on at the Seaview Hospital and for which claims of some rather miraculous cures were being made.

Because of these exaggerated claims, most physicians interested in tuberculosis were skeptical and reluctant to accept the drug as having as favorable an effect as the previously well-tested streptomycin. This skepticism was enhanced by the subsequent observations that in the first few months of treatment, patients receiving streptomycin were showing more objective evidence of improvement than were those receiving isonicotinic acid hydrazide.

As is usual in the case of new drugs, the truth lies apparently somewhere in between the two extremes. Later observations on patients receiving isonicotinic acid hydrazide reveal that after approximately four months' treatment there is little to choose between the two drugs. This also points to the fact that both drugs are being given over much longer periods than was common in the beginning, courses of twelve months or longer not being uncommon.

In order to accomplish these longer courses, it is of course necessary to combine both streptomycin and isonicotinic acid hydrazide with paraminosalicylic acid or with each other in order to delay the emergence of resistant strains of tubercle bacilli. With the present dosage schedules, this resistance factor seems to be the most important consideration at the present time, as evidence of toxicity, fortunately, is rather uncommon.

As with all other forms of treatment for tuberculosis, it has again been shown that there is no sure-fire cure. This is not to say that these chemotherapeutic agents are without value. In fact, streptomycin and isonicotinic acid hydrazide are extremely helpful. All of us are very much impressed by the almost unbelievable improvement noted in some patients receiving these drugs, patients who a few years ago would have most certainly died. In addition, we are also impressed by the amount and type of surgery which may now be done on tuberculous patients under the protection of these drugs.

However, the use of these drugs—valuable as they are—belongs in a well-integrated plan of treatment including rest, surgery and the other time-tested forms of therapy. They should be used in a sanatorium where the proper studies on resistance and toxicity may be made, and the patient properly evaluated. Eradication of tuberculosis may not occur for many years to come, but we can most certainly advance toward this goal if we use the tools at hand in the most efficient manner.

G.C.R.

---

THE DISTRIBUTION OF GAMMA GLOBULIN

WITH the approach of the poliomyelitis season, physicians will receive inquiries as to the value of gamma globulin in the prevention of poliomyelitis and who should receive it.

The profession has been recently circularized by the Minnesota Department of Health to the effect that gamma globulin has been made available through the combined efforts of the Red Cross and National Foundation for Infantile Paralysis but that its distribution is to be made through the State Department of Health. The method of distribution in Minnesota will be to inoculate contacts fifteen years of age or younger in households where poliomyelitis occurs and pregnant women of any age who are household contacts of a case during the three days prior to and the five days following the onset of the first symptoms of the disease. The physician will be able to obtain the needed gamma globulin by submitting the required data to the Minnesota Department of Health, Division of Disease Prevention and Control, on the University Campus, Minneapolis 14 (Telephone Gladstone 5973 or Prior 4574).

A statement by the Division of Medical Sciences of the National Research Council appears in part in this issue. It presents in some detail the problems involved in the control and prevention of poliomyelitis and is published for the information of the profession. It is obvious that the 15,000,000 children under the age of fifteen cannot be inoculated with the 1,000,000 doses of available gamma globulin.

As is evident, many inoculated children will develop polio, and unwarranted promises should not be made about the efficacy of gamma globulin. According to the reported series, however, there is a lower incidence of poliomyelitis in inoculated children than in control groups, which warrants the attempt to prevent or modify a comparative few poliomyelitis infections.

HAROFE HAIVRI

The Hebrew medical journal, Harofé Haivri, initiated by a group of Jewish physicians, made its appearance twenty-five years ago. The paucity of medical terms in the Hebrew language was a real handicap, and one of the principal objectives of the journal was to create a medical terminology in Hebrew.

The need for such a journal in Palestine was evident. Lists of new terms in Hebrew have appeared in each issue of the journal from the start, the new words having been contributed by those expert in Hebrew philology. In addition to new terms having been coined, old terms have been resurrected. The journal has served as a bridge between Jewish physicians in America and those in Palestine.

Thus the ancient Hebrew tongue has been adapted to the needs of modern medicine and the medical students in the Medical School of the Hebrew University in Jerusalem can take all of their courses in Hebrew.

MEDICAL SCHOOL FACULTY PUBLICATIONS

The Bulletin of the University of Minnesota Hospitals and the Minnesota Medical Foundation will contain a section listing Publications of the Medical School Faculty. The purpose of this listing is to keep the members of the faculty posted in regard to the publications of other faculty members. Faculty members are urged to transmit to Dr. Robert B. Howard, Director of the Department of Continuation Medical Education, 3330 Powell Hall, University of Minnesota, the titles, journal, volume, page number, and date, of medical articles when they appear.

DISTRIBUTION AND USE OF GAMMA GLOBULIN

During the past few months, wide publicity has been given to the results of studies indicating that a fraction of human plasma, known as gamma globulin, has some value as a prophylactic agent for paralytic poliomyelitis. As a result of this publicity, an overwhelming demand for the material may be anticipated in the coming months. The purpose of the present document is to outline the steps that have been taken to meet this situation and to discuss briefly the principles on which current plans for the distribution of gamma globulin have been based.

The supply of gamma globulin is severely limited. It is estimated that the maximum amount available this summer will not exceed 10,000 liters. Even if this were all used for the prophylaxis of poliomyelitis in children, it would provide less than one and a half million average doses. Moreover, the dose would be large enough only to give protection for four to five weeks. How inadequate is this supply to meet the demand will be evident when it is recalled that there are some 40 million children in the United States under fifteen years of age.

The situation is even less favorable than these figures indicate. Gamma globulin contributes to the public health in ways other than in the prophylaxis of poliomyelitis. It is well established as a valuable agent in the control of measles and of infectious hepatitis. It is proving its effectiveness in the treatment of the rare condition of hypogammaglobulinemia. Provision must be made to reserve amounts of gamma globulin adequate to meet these needs. Furthermore, since gamma globulin is a product derived from human blood, consideration must be given to the requirements of military and civilian services for whole blood, plasma and albumin. To maintain a well-balanced National Blood Program, blood collected by the American National Red Cross must be wisely apportioned between these varied needs.

Shortly after the outbreak of the Korean War, it was recognized that the competing demands of several Government agencies for blood and the derivatives of blood might become acute. To assure an equitable distribution, the Office of Defense Mobilization was assigned the task of co-ordinating the National Blood Program. Late in 1952, the evidence for the value of gamma globulin in the prophylaxis of poliomyelitis was first published. Realizing that this new development would lead to an extreme demand for gamma globulin during the next poliomyelitis season, the Office of Defense Mobilization turned to the National Research Council for advice. In response, the Council appointed a panel of experts in public health services, epidemiology and poliomyelitis to study the problem. There was general agreement that the equitable and effective use of available supplies of gamma globulin could be achieved only by the adoption of a system of controlled distribution. In consultation with the foremost authorities on poliomyelitis, an allocation program was devised and submitted to the Office of Defense Mobilization. The recommendations of the panel were approved in principle by the Health Resources Advisory Committee, Office of Defense Mobilization, on April 15, 1953. The plan, in the form which has been communicated to all health authorities, is attached as an appendix to this agreement. The discussion that follows is a brief review of the nature of gamma globulin, the amounts that are expected to be available this summer and the criteria on which the effective use of the material should be based.

Gamma Globulin

Gamma globulin is the name given to one of several fractions of the protein component of human plasma. It is comparable with the product officially known as immune serum globulin. Gamma globulin is prepared commercially by a method involving a series of precipitations with varying concentrations of alcohol under controlled conditions of acidity and low temperature. An average donation of blood (500 cc.) yields 7 cc. of a 16 per cent solution of gamma globulin. This represents a single recommended dose for the prophylaxis of poliomyelitis in a 50-pound (6- to 7-year-old) child.

The production capacity of existing fractionating plants is limited.

Administration.—Gamma globulin is available as a 16 per cent solution. This solution is opalescent and somewhat viscous, necessitating injection through a No. 18 or 20 needle for quantities required for the prophylaxis of poliomyelitis. Injections should be made intramuscularly, using a separate syringe and needle for each subject. Gamma globulin should never be given by the intravenous route.

The use of separate syringes is recommended because of the danger of contamination of the syringe with blood containing the virus of homologous serum hepatitis. This may occur when one attempts to withdraw blood in order to be certain that the needle point is not in a vein. It is for this reason that the repeated use of the same syringe carries the hazard of the transmission of homologous serum jaundice. No instance of hepatitis has been recorded following the use of gamma globulin which has been prepared and administered in the manner described above.

The intramuscular injection of gamma globulin is not accompanied by any significant reactions. The danger of local or systemic reactions must, however, be considered if repeated injections are contemplated.

Measles

A dose of 0.1 cc. per pound body weight, when given soon after exposure, will prevent infection in most cases. When given later in the incubation period, this dose

---

A statement by the Division of Medical Sciences, National Research Council, April 20, 1953.

will result in modification of the disease. A dose of 0.02 cc. per pound body weight will usually modify the severity of the attack if given soon after exposure to infection.

In general, modification is to be preferred to prevention. Because of the seriousness of the disease in the younger age group, it is suggested that modification be attempted in all children below the age of three years who have been exposed to infection.

Prevention rather than modification may be warranted in hospital situations involving debilitated children and in individual cases where there is concurrent serious disease such as clinically active childhood tuberculosis.

The selection of exposed children rarely presents difficulties since the contact is almost always a frank clinical case and the time of exposure can frequently be determined. A history of a previous attack of measles should suffice to distinguish immune from susceptible children, and thus determine the need for prophylaxis following exposure.

Poliomyelitis

Two reports[2,3] by Dr. W. McD. Hammon and his associates are available on the epidemiological studies which form the basis for the use of gamma globulin in the prophylaxis of paralytic poliomyelitis. The children investigated ranged in age from one to eleven years and the doses used were 4, 7 or 11 cc., depending on the weight of the child. The average dose approximated 0.14 cc. per pound body weight.

Significant protection was demonstrated from the second through the fifth week following injection and diminishing protection was evident from the sixth to the eighth week. There was no significant difference in the number of cases of poliomyelitis in the treated and control groups in the week following injection, but there was evidence of mitigation of paralysis in the cases occurring in the children who had received gamma globulin. This evidence is the basis for the conclusion that gamma globulin will be most effective if given shortly before or as soon as possible after infection. It is of no value after clinical symptoms of the disease have become apparent.[1]

Criteria for Diagnosis.—It will be noted that the basis for allocation to the States is dependent upon the reported incidence of the disease, with the suggestion that the incidence of paralytic cases may be used as a control in making additional and supplemental allocations.

To insure uniform reporting it is suggested that physicians and health departments adopt criteria for diagnosis similar to those formulated by the National Conferences on Recommended Practices for the Control of Poliomyelitis.[5] The following is an excerpt from the above document.

"Diagnostic criteria of paralytic or non-paralytic poliomyelitis should generally include three or more of the following:

1. history compatible with poliomyelitis
2. fever
3. stiff neck and/or stiff back
4. 10 to 500 cells per cc. of spinal fluid taken during the acute or early convalescent period of the disease
5. spinal fluid protein elevated above normal limits
6. demonstrable muscle weakness or paralysis.

"Cases which present only (1) history compatible with poliomyelitis, and (2) fever, should be classified as presumptive (abortive) poliomyelitis.

"Paralytic cases are defined as those in which definite weakness or paralysis has been detected and persisted during at least two examinations made at intervals of at least several hours. Results of an examination for paralysis of muscles of the extremities or trunk may be very unreliable during the period of muscle tenderness or 'spasm.'"

Community Prophylaxis.—Community prophylaxis of age groups at the greatest risk is indicated only in areas in which the incidence is exceptionally high and the onset of the epidemic is abrupt. In Hammon's studies in Harris County, Texas, where the epidemic rate was 82/100,000, only 0.4 cases were prevented per 1,000 injections. The effectiveness rose to 3.4 per 1,000 in the Iowa study where the epidemic rate was nearly 400/100,000. A further difference between these two epidemics lay in the fact that the former was prolonged over many months whereas the majority of the cases in Iowa occurred in a period of two months. The effectiveness of mass prophylaxis is proportional to the incidence of the disease in the selected age group during the few weeks following injection and is influenced by the intensity of the outbreak as distinct from its ultimate rate. Mass prophylaxis is most effective if instituted about three weeks prior to the peak of an unusually intense epidemic.

Household Contacts of Clinically Diagnosed Cases.—During epidemics, the incidence of secondary cases in families is five to twenty times the rate of poliomyelitis in the general population. That is to say, the members of a family in which a case occurs are subject to a much higher risk than are individuals in the community at large. On the basis of risk alone there would appear to be good reason to give priority to the prophylaxis of family contacts. There are, however, no controlled studies of the effectiveness of gamma globulin in the protection of household contacts of diagnosed cases. There is much evidence to indicate that infection is often widespread in families at the time the first case is recognized. If gamma globulin were effective only when given prior to infection the case for household prophylaxis would be prejudiced. Hammon's results suggest, however, that inoculation after infection but prior to the onset of symptoms may be expected to modify the disease although it may not prevent it.

It has been observed that 60 per cent of secondary cases within a household occur within five days of the diagnosis of the first case. Even if gamma globulin is administered promptly to the household contacts, it will not be expected to prevent or modify the severity of disease in these cases. An additional 30 per cent of the secondary cases will occur within a few days of inoculation. Hammon's results suggest that this group of cases may be mitigated in severity.

The final 10 per cent of secondary cases will occur in the period in which the protective effect of gamma globulin is maximal and it is this fraction of cases that one may hope to prevent by the use of household prophylaxis. This would, at first sight, appear to be a poor return on the investment were it not a fact that the rates for this small fraction of delayed cases are comparable with the rates among all children in epidemic areas. On this basis, household prophylaxis may be expected to be as effective (cases prevented per 1,000 doses of gamma globulin) as community prophylaxis in the prevention of epidemic poliomyelitis and may be more effective if weight is given to modification as well as prevention of the disease. In areas in which epidemic proportions have not been attained, there will be no justification for general community prophylaxis.

Intimate Contacts of Clinically Diagnosed Cases.—This is simply an extension of household prophylaxis to include individuals who are judged to have been as intimately associated with the diagnosed case as were the members of the household. The extension is logical but raises the difficulty of defining the criteria of intimacy. The method is likely to be most useful in rural and in self-contained suburban communities in which the number of intimate contacts of an individual is limited.

The extension of prophylaxis from household contacts to equally intimate contacts must be used with restraint; otherwise, the allocations to States will be rapidly depleted. It is anticipated that the responsibility for the definition of extra-household contacts and the areas within the State in which this method of prophylaxis may be used to advantage will rest with the State Health Officer.

Household Contacts of Suspected Cases.—The immunization of household contacts of suspected cases may be viewed as a selective form of community prophylaxis which is specifically directed toward those individuals in the community subject to the most intimate exposure to the virus of poliomyelitis at the time that prophylaxis is undertaken. The use of this method is advocated only in intense epidemic situations. It may be particularly valuable in sparsely populated areas in which sporadic cases lead to extremely high rates of incidence but which are not suited to mass prophylaxis.

The method has the merit of giving protection to individuals who may be exposed to infection several days earlier than would be possible were the injections delayed until the physician could make a more certain diagnosis. There is a further hypothetical advantage which is of quite undetermined value although it may be most significant. Infection with the poliomyelitis virus is much more likely to be abortive than paralytic. It follows that the first invasion of a family by the virus is probably evidenced only by a case of minor illness. Should the case actually be one of poliomyelitis, immunization of the family at this time may prevent any paralytic case from developing.

The prophylaxis of contacts of suspected cases has serious disadvantages. Its efficacy is just as dependent as is that of community prophylaxis on the accurate prediction of epidemic conditions. If it is used in other than epidemic areas, much gamma globulin will be squandered on contacts of minor illnesses, a negligible proportion of which are poliomyelitis infections.

The method has been described as a selective form of community prophylaxis. It differs in that the office of every physician in the area will become a prophylactic clinic. From one point of view, this will simplify administration by avoiding the problems that are associated with the organization of centralized clinics. On the other hand, if a significant fraction of the total population in the area is involved, it may overtax the physicians and result in undesirable delay in completing the required number of injections.

Summary

It is estimated that about 1,000,000 average doses of gamma globulin will be available for the prophylaxis of poliomyelitis during 1953. The selection of the group of individuals in which this limited supply of material can be used most effectively presents many epidemiological and administrative problems. Four alternative methods have been recommended by the Division of Medical Sciences, National Research Council, and have been incorporated in the allocation plan adopted by the Office of Defense Mobilization. The advantages and disadvantages of these methods in particular situations are reviewed. The allocation plan is based on the principle that it is the local health officer who is in the best position to decide which method of prophylaxis will most effectively meet each local situation as it arises.

The household contact plan would appear to be the most effective in areas of low or moderate incidence, with possible extension to include intimate contacts other than family members. With high epidemic incidence in a community with an intense outbreak, either community prophylaxis of age groups particularly susceptible or extension of the household contact plan to include contacts of suspected cases may be suitable. Factors such as community size, expected severity and duration of the epidemic, facilities for the injection of large numbers of individuals and the availability of gamma globulin may influence the decision as to the plan for emphasis in a particular area.

The plans are of sufficient latitude, however, to apply to almost any situation, and appear to offer some hope of restricting the use of the scarce material to the groups at greatest risk.

CHANGE IN VITAL STATISTICS LAW TO AFFECT PHYSICIANS BEGINNING JULY 1, 1953

Physicians must be aware of a fundamental change in the Vital Statistics Law which affects birth and death registration in townships and villages and in certain cities beginning with July 1, 1953.

The amended Vital Statistics Law provides:

1. That villages and townships cease to be primary registration districts for birth and death registration purposes.
2. That cities may remain as primary registration districts if they elect by ordinance to continue local registration of births and deaths.
3. That each county will be a primary registration district.
4. That local registrar in each county will be the Clerk of the District Court, and the local registrar in each city adopting a registration ordinance will be the Health Officer.
5. BIRTH CERTIFICATES FOR CHILDREN BORN OUT OF WEDLOCK WILL CONTINUE TO BE FILED WITH THE STATE REGISTRAR, DR. A. J. CHESLEY, SAINT PAUL.

Physicians filing birth certificates on or after July 1, 1953, without respect to date of birth, must file them as provided by the amended Vital Statistics law which reads as follows:

Minnesota Statutes 1949, Section 144.151 and 144.157 as amended by Chapter 309, Laws of 1953.

Section 144.154.—For the purpose of sections 144.151 to 144.204, each city which by ordinance elects to maintain local registration of vital statistics and each county shall constitute a primary registration district. The state registrar may establish registration districts on United States government reservations and appoint local registrars for them.

Section 144.157. Subd. 1.—In the cities which by ordinance elect to maintain local registration of vital statistics the health officer shall be the local registrar. In counties the clerk of the district court shall be the local registrar.

ANALYSIS OF TUBERCULOSIS CASE REGISTERS IN MINNESOTA

(Continued from Page 486)

December 31, 1951; June 30, 1952; and December 31, 1952. Through the co-operation of the agencies concerned, considerable progress has been made in simplifying and clarifying the reports, so that for the first time a reasonably accurate tabulation is possible of several basic factors.

The analysis has included only the file of current cases as contrasted to the file of closed cases. A current case in a tuberculosis register is one which is administratively active in the sense that the case is under current medical supervision or in need of such supervision. Some agencies with well-developed health organizations can extend supervision to more cases of tuberculosis and for longer periods than can be done by other jurisdictions, but in either instance the cases included in their current files represent the work load of tuberculosis recognized by the agency as their primary problem. Thus, in the fifteen years from 1938 through 1952, 42,273 cases of tuberculosis were reported to the State Health Department in Minnesota. Many of these individuals have since died, been lost track of, moved out of the state, healed, or are in no need of supervision. Yet, as of December 31, 1952, as shown in the attached tables, 12,795 cases of tuberculosis were still in the current files of health agencies in the state, and presumably were receiving supervision to some degree so that they were administratively active.

In classifying cases of tuberculosis from the clinical standpoint, the uniform terms and definitions published every ten years by the National Tuberculosis Association have been accepted and employed by most reporting agencies and are used in the register analysis here described. Thus, of the total 12,795 current cases of tuberculosis, 10,969 are classified as pulmonary tuberculosis, and include 700 non-white persons. From the standpoint of clinical activity of the disease itself, 2,026 pulmonary cases are clinically active and thus potential sources of new infections. As of December 31, 1952, 509 of these active pulmonary cases were at home or somewhere other than in hospital, and an additional 109 clinically active cases of non-pulmonary tuberculosis were recorded as outside of hospitals and sanatoria.

These are the more striking findings that appear from looking at the records. Undoubtedly, many of the cases now included in current files could be properly transferred, after review, to closed files, thus decreasing the apparent tremendous burden of tuberculosis cases that continue to need supervision. More important, however, and the real key to eventual elimination of tuberculosis, is the great need to strengthen and expand the services of all health agencies concerned so that more supervision of more cases, both current and closed, can be provided. By more frequent physical examinations, x-rays, and health supervision, current cases will become noninfectious for others, and closed cases that break down and become clinically active will be discovered earlier. Early discovery of infectious cases and prevention of spread of the disease to new victims remain the keystones to tuberculosis control.

Medical Economics

Minnesota State Medical Association
George Earl, M.D., Chairman

REORGANIZATION PLAN GOES INTO EFFECT

The Eisenhower administration's Reorganization Plan No. 1, of 1953 has gone into effect, with the sanction and blessing of the House of Delegates of the American Medical Association, which group also put an important reservation on the operation of the plan.

The reorganization plan transfers all functions of the Federal Security Administration into the new executive department, officially titled the Department of Health, Education and Welfare. The new department will also have a Special Assistant to the Secretary of Health and Medical Affairs, and the plan provides: "There shall be in the Department a Special Assistant . . . who shall be appointed by the President by and with the advice and consent of the Senate from among persons who are recognized leaders in the medical field with wide non-governmental experience, shall review the health and medical programs of the Department and advise the Secretary with respect to the improvement of such programs and with respect to nesessary legislation in the health and medical fields, and shall receive compensation at the rate now or hereafter provided by law for assistant secretaries of executive departments."

The acceptance of the plan by the AMA House of Delegates marks a new departure for that group, for, up to this time, organized medicine has officially supported the creation of a separate Department of Health.

However, serious thought and plenty of heated discussion were enough to prompt delegates to vote for the plan. Meeting in special session on March 14, the delegates voted approval of the administration plan to create a Department of Health, Education and Welfare.

The meeting was highlighted by the appearance of important personages: President Eisenhower, Senator Taft, Mrs. Oveta Culp Hobby, and many officials from the American Medical Association.

President Eisenhower spoke to the delegates in his usual winning manner, asserting that he felt that decisions would be reached that would be for the good of the people of the United States. He stated his faith in Americans' wish to do the right thing, and expressed his confidence that doctors will provide needed medical services, but that they will do so much better with the cooperation and friendship of the administration rather than by its direction or under that of any big "poobah" in this field.

Senator Taft and Congressman Walter Judd both appeared in support of the reorganization plan.

The plan had been submitted to Congress on March 12, thereby foregoing the probability of the creation of a separate Department of Health. According to Dr. Louis H. Bauer, president of the American Medical Association, since there was then no possibility of getting a separate health department, "we were all anxious to see that the best possible status be established for health and medicine." Dr. Bauer reports the new special assistant's responsibilities as follows:

> "As a result the reorganization plan introduced provided a new position, that of a special assistant to the Secretary. All medical activities within the new department, as well as all medical phases of any activities within education or social security, must be cleared through this special assistant to the Secretary. This will include appropriations and budgets as well as policies. The same special assistant will also be the representative of the Secretary at all interdepartmental meetings at which health will be a topic for discussion and also at congressional hearings where appropriations involving health will be discussed. Furthermore, this special assistant must be selected from among persons who are recognized leaders in the medical field. . . . This gives medicine a status of dignity and control over medical affairs, subject only to action of the Secretary."

Resolution Adopted

The resolution which the House of Delegates adopted on March 14, explains previous stands and gives adequate reasons why a new position has been taken. It states:

> "The House of Delegates of the American Medical Association has for nearly 80 years been on record as favoring an independent Department of Health in the federal government. The reason for this stand has been that the House felt that health and medicine should be given a status commensurate with their dignity and importance in the lives of the American people, and that they should be completely divorced from any political considerations.
>
> "The Board of Trustees . . . finds that Reorganization Plan No. 1 of 1953, provides for a special assistant to the Secretary for Health and Medical Affairs. This provision is a step in the right direction which should result in centralized co-ordination under a leader in the medical field of the health activities of the proposed department. Health, therefore, is given a special position. The proposed plan, properly administered, will permit more effective coordination and administration of the health activities of the new Department without interference or control by other branches.
>
> "Previous attempts to raise the Federal Security Agency from an independent agency to the level of an Executive Department have been opposed by the Association because the plan did not meet these aims."

Reaffirms Old Stand

Although the House of Delegates supported Eisenhower's new plan, it firmly stated its preference for a completely independent Department of Health: "The Board of Trustees recommends that the House of Delegates reaffirm its stand in favor of an independent Department of Health but that it support the Reorganization Plan No. 1 of 1953, as being a step in the right direction; that the American Medical Association cooperate in making the plan successful and that it watch its development with great care and interest."

Reservation Included

The statement passed by the House also presented, in no uncertain terms, a reservation of the right to make recommendations to amend any part of the creative legislation which does not live up to certain principles:

> "It should be understood, however, that the Association reserves the right to make recommendations for amendment of the then existing law or to press for the establishment of an independent Department of Health, if the present plan does not, after a sufficient length of time for development, result in proper advancement in and protection of health and medical science and in their freedom from political control."

General agreement exists that the House of Delegates made a wise decision by passing this resolution. The very fact that the medical profession literally reversed itself in this matter, should prove that physicians as an organized group do not always take a negative position, and that when they believe in something, they take action to protect it. Dr. Bauer summed up by saying, "Now . . . we shall be embarking on a new sea of adventure, and I believe the medical profession of the United States can wield a constructive influence on the health of the American people. I am sure that we shall have every possible cooperation from Washington. The address of the President of the United States to the House of Delegates certainly assured us of that."

AMA MEETING PLANNED FOR NEW YORK

The 102nd annual meeting of the American Medical Association is scheduled for June 1-5, in New York. According to the *Journal of the American Medical Association* announcing the meeting, there will be over 400 scientific papers, 260 scientific exhibits, 370 technical exhibits and daily motion picture and television programs. All major specialties in medicine will be represented on the program in some one of the twenty sections.

The exhibits will be located on four adjacent floors of New York's Grand Central Palace. The general meetings of the Scientific Assembly will take place at the Commodore Hotel. The color television will originate from operating rooms and clinics of the New York Hospital and will be viewed on two 5 x 6 foot screens in the Hendrick Hudson room of the Roosevelt Hotel. The American Medical Association House of Delegate sessions will be held in the Grand Ballroom of the Waldorf-Astoria Hotel.

Social and sports events have been arranged, as usual, and all Association members are invited to participate in these functions. Auxiliary meetings are scheduled in conjunction with the doctors' meetings. Complete detailed accounts of meeting arrangements will be found in the April 11 issue of the *Journal of the American Medical Association.*

NATIONAL HEALTH COUNCIL REVIEWS COMMISSION REPORT

Delegates to the National Health Council meeting in New York on March 19, considered the report of the President's Commission on the Health Needs of the Nation. The Council is made up of some forty member organizations, of which the American Medical Association is one. Of late there has been considerable doubt about the general tone of the statements of the Council, and, as a result, some member groups have withdrawn support.

The meeting was divided into groups, each considering certain phases of the commission's report: "Paying the Bill for Personal Health Services," "Meeting the Needs for Health Personnel," "Building Better Health Facilities, " "Organizing Health Services More Effectively," and "Fostering Research for Better Health."

The meeting was well attended, and interest ran high—especially in the group whose topic was devoted to financial considerations in medical care. The discussion was thorough, and much objection was evident over the general statements and conclusions of the Commission. There was sentiment that the Commission had failed to close the door to consideration of compulsory health insurance as an answer to health needs problems, even though individual Commission members had supposedly expressed opposition to it.

The meeting, lively as it was, passed no official sanction or denunciation of the report of the President's Commission on the Health Needs of the Nation. Representatives from the American Medical Association and from many state medical associations were in attendance, and their opinions and ideas about the report were strongly expressed and accepted by the conference as a whole.

FEDERAL GOVERNMENT UNDERWRITES INSURANCE

The United States' government is in the insurance underwriting business—not underwriting insurance for its own activities, but doing it for risks to which private property and private business activities are exposed.

According to a recent issue of "Insurance Economics Surveys" the government is conducting eleven major insurance operations, spread over the fields of life insurance, pensions, financial guarantees and property insurance of all kinds. The report states:

> "The liability which the Federal Gvernment has assumed to pay death benefits under the social security law is greater than the entire amount of private life insurance in force, while the Government's liability to pay pensions under social security is estimated at 10 to 15 times greater than all of the annuity business on the books of the private insurance companies."

It is also interesting to note, the report states, that the taxes collected by the social security system for these two kinds of benefits are little more than one-third of the amount of premium income collected by the private life insurance companies.

The report quotes the eleven fields of government underwriting activities as:

1. Life insurance for men in the armed services and veterans.
2. Marine and aviation war risk insurance.
3. Old age and survivors insurance.
4. Railroad employes' retirement system.
5. Civil service employes' retirement system.
6. Unemployment compensation.
7. Federal employes' compensation
8. Crop insurance.
9. Insurance of commodities under Commodity Credit Corporation loans.
10. Guarantees of bank and other depositories.
11. Guarantees of mortgage loans.

VACCINES NOT PROVED

Poliomyelitis vaccines must be proved both effective and safe before public health authorities will be convinced of their acceptability. No polio vaccine has yet been proved both effective and safe, nor can the safety of such a vaccine be determined until it has been tested on a large enough group—preferably from 50,000 to 70,000 children. There are three distinct strains of polio virus, and no vaccine available at present will protect against all three. A really safe vaccine must be safe for the unusual individual, not merely for the majority. A vaccine that is safe for only 990 children out of a thousand is "worse than a polio epidemic."

These were some of the comments made by Dr. Gaylord W. Anderson, director of the School of Public Health, University of Minnesota, speaking at Hennepin County Health Day on "Can We Prevent Polio?" Ultimate solution of the polio problem will probably be a vaccine, said Dr. Anderson, but he added that "our hopes have been raised a bit prematurely." It is unlikely, he added, that either a safe vaccine or sufficient supplies of gamma globulin for preventing or modifying the effects of polio will be available in the near future.—*Minnesota's Health,* March, 1953.
